No. 4

## NEW STEPHANIDÆ FROM BORNEO AND THE PHILIPPINE ISLANDS, III

By E. A. ELLIOTT

*Fellow of the Zoological Society of London and of the Entomological  
Society of London*

### Subfamily DIASTEPHANUS

This subfamily shows the lowest form of development of the neururation. The group in which the anterior frontal tubercle is wanting and that in which the two femoral teeth are white appear to be closely related, differing chiefly in the proportions of the basal antennal joints, the presence or absence of a border to the posterior margin of the head, and, in a lesser degree, in details of sculpture and color. The substitution of bristles for the usual smaller teeth or serrations at the base of the femora, behind the first large tooth, occurs in many species, but the entire substitution, between and in front of the large teeth, in only a very few species.

#### *Key to species of Diastephanus.*

20. 1. Hind femora tridentate.
11. 2. All femoral teeth white.
8. 3. With small teeth between the larger ones.
5. 4. Frons apically white, the upper border forming a W.  
**D. trialbatus** sp. nov.
4. 5. Head otherwise colored.
7. 6. Head black, frons ferrugineous to flavous, vertex and occiput transstriate to rugose; metapleuræ and median segment confluent..... **D. pallescens** Schletterer.

6. 7. Head rufescent, frons and cheeks flavescent; occiput centrally punctate; metapleuræ and median segment separated by a carina..... *D. multicolor* sp. nov.
3. 8. Small teeth between larger ones replaced by bristles.
10. 9. Head red-brown, part yellow; red spot on second tergite; hind metatarsi white ..... *D. flavifrons* Kieffer.
9. 10. Head black, part white, white spot on second tergite; hind metatarsi rufous..... *D. leucostictus* Kieffer.
2. 11. Hind femoral teeth not all white.
13. 12. Two apical teeth white, the basal brown or black.  
*D. annulipes* sp. nov.
12. 13. All femoral teeth concolorous with femora.
15. 14. Occiput and neck very short..... *D. curticollis* sp. nov.
14. 15. Occiput and neck more or less elongate.
17. 16. Hind coxæ cylindrical; frons, vertex, and occiput finely and evenly transstriate..... *D. lucifer* sp. nov.
16. 17. Hind coxæ clavate.
19. 18. Frons granulate rugose, mesonotum transrugose, second abdominal segment not elongate..... *D. elongatus* sp. nov.
18. 19. Frons coarsely arcuate striate, mesonotum nearly smooth; second abdominal segment much elongate..... *D. longior* sp. nov.
1. 20. Hind femora bidentate.
32. 21. Femoral teeth white.
25. 22. Anterior frontal tubercle present.
24. 23. Hind coxæ normal.
- 23b. 23a. Terebra longer than body, white-banded..... *D. levis* sp. nov.
- 23a. 23b. Terebra as long as body, black..... *D. punctinotum* sp. nov.
23. 24. Hind coxæ strongly clavate; terebra shorter than body, rufescent.  
*D. clavicoxis* sp. nov.
22. 25. Anterior frontal tubercle obsolete.
29. 26. Posterior margin of head bordered.
28. 27. Frons arcuate striate, vertex and occiput rugose; third flagellar joint much longer than first and second together; petiole shorter than rest of abdomen..... *D. albidens* Kieffer.
27. 28. Frons and occiput finely, vertex coarsely transstriate; antennæ normal; petiole as long as rest of abdomen.  
*D. albonotatus* Elliott.
26. 29. Posterior margin of head not bordered.  
*D. flavonotatus* Elliott.
31. 30. White or flavous spot on third abdominal segment.  
*D. leucodontus* Schletterer.
30. 31. No spot on third segment.....
21. 32. Hind femoral teeth concolorous with femora.
36. 33. Frons, vertex, and occiput finely transstriate.
35. 34. Posterior margin of head bordered; terebra rufescent.  
*D. parvulus* sp. nov.
34. 35. Posterior margin of head simple; terebra white-banded.  
*D. semiglaber* sp. nov.
33. 36. Head differently sculptured.
33. 37. Frons, vertex, and occiput arcuate striate; mesonotum with three longitudinal impressions; hind coxæ strongly clavate.  
*D. clavatus* sp. nov.

37. 38. Frons arcuate costate, vertex and occiput finely transstriate; mesonotum without the usual impressions; coxæ normal.

*D. costifrons* sp. nov.

*DIASTEPHANUS TRIALBATUS* sp. nov., female and male.

*Male*.—Frons apically transstriate, basally more granulately, with a few punctures, posterior tubercles distinct, four carinæ on vertex, behind which it is finely transstriate, then superficially punctate, occiput basally smooth, posterior margin of head strongly bordered; scape as long as cheeks and, like the first flagellar joint, stout, second joint scarcely longer than first, third nearly as long as first and second together; pronotum finely transstriate, becoming gradually finer toward the smooth base; mesonotum with three rows of punctures very close together, lateral angles feebly rugose; scutellum centrally smooth, lateral lobes indistinctly sculptured and dull; mesopleuræ smooth; metapleuræ coarsely punctate, separated apically only by a more or less distinct carina from the median segment, which is centrally superficially and diffusely, apically and laterally more closely punctate and dull; petiole transstriate, shorter than the remaining smooth shining segments. Hind coxæ transstriate, femora extremely finely transaciculate, tridentate, tibiæ compressed in basal two-thirds, metatarsi scarcely longer than the remaining joints. Radius emitted from apical fifth of stigma, its distal section twice as long as the proximal.

Black; head beneath, cheeks, outer orbits, and frons to about the level of the middle of the eyes white, above this the frons is black, the junction of the two colors forming a distinct W; apices of tubercles and the carinæ on vertex bright red, rest of head black; two or three antennal joints and the anterior legs rufotestaceous, apices of hind coxæ and femora, a spot on each side of second tergite, the femoral teeth and hind metatarsi white; nervures red-brown.

*Female*.—Agrees in sculpture with the male, but the frons is apically flavous, passing into reddish, and the black color does not come down quite as low and is less sharply demarcated. Terebra rufescent, shorter than body.

Length, male, 7 to 8.5 millimeters; abdomen, 4.5 to 5; petiole, 2. Female, 9.5 millimeters; abdomen, 5.5; petiole, 2.5; terebra, 8.

BORNEO, Sandakan (*Baker*).

This species belongs to the small group with three white femoral teeth. The sculpture of the head and median segment is distinctive, as is also the striking marking of the frons, in which

it resembles my *D. albifrons* which, however, has bidentate femora with concolorous teeth.

**DIASTEPHANUS PALLESCENS** Schletterer, female and male.

*Diastephanus pallescens* SCHLETTERER, Berl. Ent. Zeit. 33 (1889) 123, female.

*Male*.—Frons finely, indistinctly transrugose, occiput coarsely granulate rugose; posterior tubercles broad, posterior margin of head bordered; scape slightly longer than cheeks, antennæ about normal; neck elongate, finely transstriate, semiannular basally smooth; mesonotum irregularly rugose, central line of punctures distinct; scutellum centrally dull, lateral lobes lightly punctate; mesopleuræ smooth; metapleuræ and median segment indistinctly separated, reticulate punctate, former more coarsely; petiole transstriate, shorter than rest of abdomen. Hind coxæ transstriate, femora finely transaciculate, rather dull, tibiæ longer than femora, compressed in basal two-thirds, metatarsi about as long as the remaining joints. Radius emitted from near apex of stigma, its distal section about twice as long as the proximal.

Black; mandibles except apices, head beneath, frons, and scape flavescent, remainder of head red; flagellum basally rufescent, becoming black toward apex; anterior legs and hind trochanters rufescent; middle metatarsi basally and hind ones entirely whitish; femoral teeth white. All nervures rufescent.

Length, 10 millimeters; abdomen, 6.5; petiole, 3.5.

BORNEO, Sandakan (*Baker*).

I have little doubt that this is the male of Schletterer's *D. pallescens*. The sculpture is somewhat finer, but agrees in all essentials.

**DIASTEPHANUS MULTICOLOR** sp. nov., male.

*Male*.—Frons elongate, subgranulately, vertex and occiput evenly transstriate, latter centrally with large superficial punctures and longitudinal impression, posterior margin of head bordered finely, posterior tubercles broad, three carinæ behind posterior ocelli; scape as long as cheeks, antennæ normal; pronotum finely transaciculate, basally narrowly smooth, neck elongate, basal half longitudinally impressed; mesonotum centrally smooth, laterally slightly rugose, central row of punctures distinct, lateral ones basally only; scutellum centrally smooth, lateral lobes lightly punctate; mesopleuræ smooth, basally transaciculate, metapleuræ diffusely punctate above, laterally rugose,

separated by a carina and a crenulate sulcus from the reticulate punctate median segment; petiole transstriate, shorter than the remaining smooth shining segments. Hind coxæ transstriate, femora and tibiæ transaciculate, the former tridentate, latter compressed in basal two-thirds, metatarsi not much longer than the remaining joints. Radius emitted from apical fourth of stigma, its distal section one and a half times as long as the proximal.

Black; base of mandibles, frons, cheeks, and head beneath flavescent, rest of head rufescent; pronotum centrally longitudinally black, laterally red, rufotestaceous beneath; petiole apically, second and third segments basally, and the hind legs rufescent, anterior legs light red, middle and hind metatarsi yellowish; femoral teeth distinctly white on one leg, more rufescent on the other.

Length, 10 millimeters; abdomen, 6; petiole, 2.5.

BORNEO, Sandakan (*Baker*).

**DIASTEPHANUS FLAVIFRONS** Kieffer, female and male.

*Diastephanus flavifrons* KIEFFER, Philip. Journ. Sci. § D 11 (1916) 408, male.

Kieffer knew only the male, and I only tentatively place here one female. It agrees well with the description of the male; the median segment may be somewhat more punctate; the terebra is shorter than the body, rufescent, and the spot on third tergite obsolete.

A male from Sandakan and one from Butuan differ in having the head light red and the pale marks on abdomen barely perceptible.

Length, male, 6 to 8 millimeters. Female, 7.5 millimeters; abdomen, 5; petiole, 2; terebra, 7.

BORNEO, Sandakan. MINDANAO, Butuan (*Baker*).

**DIASTEPHANUS LEUCOSTICTUS** Kieffer, female and male.

*Diastephanus leucostictus* KIEFFER, Philip. Journ. Sci. § D 11 (1916) 409, female and male.

These specimens agree with Kieffer's description in sculpture and in the general color; the white on the head is often more restricted, the vertex sometimes nigrescent, and the anterior femora rarely dorsally darker. This and the preceding species have the usual small denticulations between the large teeth on hind femora replaced by bristles and are very much alike; the chief differences appear to lie in the proportions of the basal

antennal joints, the point of emission of the radius, and in the color.

BORNEO, Sandakan (*Baker*).

*DIASTEPHANUS ANNULIPES* sp. nov., female.

*Female*.—Frons basally arcuately, apically transversely striate, vertex and occiput finely transstriate, latter basally smooth with fine longitudinal impression, three carinae on vertex, posterior tubercles distinct, ocellar space finely striate, posterior margin of head bordered; scape as long as cheeks, antennae normal; neck elongate, finely transstriate, basally almost smooth, semiannular apically transstriate, basally broadly smooth; mesonotum rugose, with three fine, feebly punctate impressions; scutellum smooth; mesopleurae smooth above, otherwise feebly punctate; metapleurae and median segment confluent, rather irregularly reticulate punctate; petiole transstriate, very little shorter than the remaining smooth, shining segments; terebra shorter than body, black. Hind coxae transstriate, subclavate, rather longer than the finely transaciculate, tridentate femora, tibiae smooth, shining, compressed to middle, metatarsi half as long again as the remaining joints. Radius emitted from apical fifth of stigma, its distal section half as long again as the proximal.

Black; head and two or three basal antennal joints red, anterior legs rufotestaceous, middle tibiae and metatarsi basally white-ringed, hind tarsi rufescent; the two basal femoral teeth white, the apical black or red. Wings hyaline, nervures and stigma red-brown.

Length, 11 millimeters; abdomen, 6.5; petiole, 3; terebra, 9.

SINGAPORE. BORNEO, Sandakan (*Baker*).

Distinguished by the peculiar color of the femoral teeth and by the sculpture of the head.

*DIASTEPHANUS CURTICOLLIS* sp. nov., female.

*Female*.—Frons finely transstriate, vertex and the very short occiput subgranulately transstriate, two inconspicuous carinae between the posterior ocelli, posterior margin of head simple, posterior tubercles distinct; scape shorter than cheeks, antennae normal; pronotum short and smooth, neck barely half as long as the semiannular; mesonotum centrally smooth, with three fine longitudinal impressions, laterally slightly rugose; meso- and metapleurae smooth, latter apically punctate, separated by an incomplete carina from the median segment, which is centrally

longitudinally punctate, otherwise smooth and rather dull; petiole finely transstriate, very little shorter than the remaining smooth shining segments; terebra longer than body, rufescent. Hind coxæ coarsely transrugose, about as long as the smooth, inflated, tridentate femora, tibiæ longer than the femora, compressed in basal two-thirds, metatarsi twice as long as the remaining joints. Radius emitted from apical third of stigma, its basal section three times as long as the proximal.

Black; frons and three or four basal antennal joints rufotestaceous, outer orbits whitish, vertex and occiput black, the carinæ red; legs except coxæ rufescent, middle tibiæ basally and apically white, front metatarsi, middle and hind tarsi except apex flavous. Stigma and nervures rufescent; femoral teeth concolorous with femora.

Length, 7 millimeters; abdomen, 4.5; petiole, 2; terebra, 10.

MINDANAO, Iligan (*Baker*).

Characterized by the short occiput and pronotum, simple posterior margin of head, inflated femora, smooth metapleuræ, and by the color of the legs.

*DIASTEPHANUS LUCIFER* sp. nov., female.

*Female*.—Frons, vertex, and occiput very finely subgranulately transstriate, vertex laterally indistinctly punctate, occiput basally narrowly smooth, posterior margin of head bordered, all tubercles small and rounded, carinæ on vertex indistinct; scape as long as cheeks, basal flagellar joints short, second little longer than first, third shorter than first and second together; neck rather long, pronotum finely transstriate, basally narrowly smooth; mesonotum short, slightly rugose, with a central impression only; central lobe of scutellum smooth and shining, the lateral lobes finely punctate and dull; mesopleuræ smooth and shining, metapleuræ coarsely, diffusely punctate, separated by a carina from the superficially reticulate punctate median segment; petiole extremely finely transstriate, shorter than the remaining smooth shining segments; terebra rufescent, as long as body. Hind coxæ cylindrical, basally irregularly rugose, apically transstriate, slightly longer than the finely transaciculate, tridentate femora, tibiæ longer than femora, the basal two-thirds compressed and transaciculate, metatarsi twice as long as the remaining joints. Radius emitted from near apex of stigma, its distal section half as long again as the proximal.

Black; face, frons, and four basal antennal joints testaceous, rest of head more rufotestaceous, prothorax beneath and anterior

legs rufotestaceous, femora darker, middle and hind metatarsi white; nervures black. Femoral teeth concolorous with femora.

Length, 8 millimeters; abdomen, 5; petiole, 2; terebra, 8.

BORNEO, Sandakan (*Baker*).

Characterized by the sculpture of the head and hind legs, and by the cylindrical hind coxæ. The whole insect very bright, excepting lateral lobes of scutellum.

*DIASTEPHANUS ELONGATUS* sp. nov., male.

*Male*.—Frons granulate rugose, vertex and occiput finely transstriate, latter with fine longitudinal impression, posterior margin of head very finely bordered, posterior tubercles small but distinct; scape as long as cheeks, second flagellar joint fully twice as long as first, third not quite as long as first and second together; neck elongate, transstriate, semiannular basally smooth; mesonotum transrugose with central impression only indicated; scutellum centrally smooth with fine marginal punctures, lateral lobes punctate; mesopleuræ smooth; metapleuræ and median segment confluent, cribrate punctate; petiole very finely transstriate, longer than the remaining smooth segments. Hind coxæ transstriate, strongly clavate, slightly longer than the tridentate femora, trochanters elongate, tibiæ not much longer than femora, compressed to beyond middle, metatarsi scarcely longer than the remaining joints. Radius emitted from apical fourth of stigma, both sections about equal in length.

Black; head beneath, mandibles basally, face, frons apically and scape rufotestaceous, remainder of head black, basal flagellar joints rufous; legs rufescent, anterior tibiæ paler; femoral teeth concolorous with femora.

Length, 12 millimeters; abdomen, 8; petiole, 4.75.

BORNEO, Sandakan (*Baker*).

*DIASTEPHANUS LONGIOR* sp. nov., male.

*Male*.—Frons coarsely arcuate striate, vertex and occiput finely and closely transstriate, posterior margin of head bordered, ocellar space striate, two inconspicuous carinæ behind posterior ocelli, all tubercles distinct; scape fully as long as cheeks, twice as long as first flagellar joint, second twice as long as first, third as long as first and second together; neck long and slender, extremely finely transstriate, appearing almost smooth, semiannular smooth and shining; mesonotum nearly smooth, with central impression only; scutellum and mesopleuræ smooth and shining; metapleuræ and median segment confluent, cribrate punctate; petiole finely transstriate, slightly longer than the re-

maining smooth shining segments, abdomen elongate, especially second segment. Hind coxæ finely transstriae, apically clavate, longer than the smooth tridentate femora, tibiæ little longer than femora, compressed about to middle. Radius emitted from apical fourth of stigma, its distal section little longer than the proximal.

Black; frons apically flavous, outer orbits white, two or three basal antennal joints rufous, anterior legs rufotestaceous, femora dorsally darker, hind legs rufescent, femoral teeth concolorous with the femora.

Length, 10 millimeters; abdomen, 6.5; petiole, 3.5.

MINDANAO, Davao (*Baker*).

Resembles my *D. elongatus*, but the neck is longer and slenderer, as is also the abdomen, especially the second segment, and the sculpture of the mesonotum and shape of hind coxæ differ greatly.

DIASTEPHANUS LEVIS sp. nov., female.

*Female*.—Frons, vertex, and occiput finely transstriae, latter basally almost smooth, posterior margin of head bordered, two indistinct carinæ between posterior ocelli, posterior tubercles broad; scape shorter than cheeks, antennæ normal; neck elongate, finely transstriae, semiannular smooth; mesonotum short, indistinctly rugose punctate, central impression basally distinct, the lateral ones obsolete; scutellum smooth, with a few punctures; mesopleuræ smooth and shining, basally transaciculate; metapleuræ and median segment confluent, superficially and rather irregularly reticulate punctate; petiole finely transstriae, as long as the remaining smooth segments; terebra as long as body, white-banded. Hind coxæ finely transstriae, apically almost smooth, longer than the bidentate, finely transaciculate femora, tibiæ much longer than femora, compressed to beyond middle, metatarsi rather more than twice as long as the remaining joints. Radius emitted from apical fifth of stigma, its distal section one and a half times as long as the proximal.

Dark red; fourth abdominal segment black; head, three basal antennal joints, anterior legs, hind coxæ, and abdomen apically beneath rufotestaceous, hind legs darker; middle metatarsi, the second joint, and the femoral teeth white. Stigma and nervures red-brown.

Length, 10 millimeters; abdomen, 6; petiole, 3; terebra, 10; band, 1.5; apex, 0.75.

MINDANAO, Dapitan (*Baker*).

Characterized chiefly by the fine sculpture, banded terebra, and rufoflavous hind tarsi.

**DIASTEPHANUS PUNCTINOTUM** sp. nov., female.

*Female*.—Frons basally arcuately, apically transversely striate, vertex and occiput very finely transstriate, posterior margin of head bordered, all tubercles well developed, one carina between posterior ocelli; scape shorter than cheeks, inflated, second flagellar joint not much longer than first, third longer than first and second together; pronotum finely transstriate, basally narrowly smooth; mesonotum centrally coarsely, almost reticulate punctate, laterally rugose, longitudinal rows of punctures wanting; scutellum and mesopleuræ smooth, rather dull; metapleuræ and median segment confluent, reticulate punctate; petiole extremely finely transstriate, much shorter than the remaining smooth, rather dull segments; terebra about as long as body, black. Hind coxæ transstriate, femora smooth, bidentate, tibiæ little longer than femora, compressed to far beyond middle; metatarsi three times as long as the remaining joints. Radius emitted from apical fifth of stigma, its distal section one and a half times as long as the proximal.

Black; head, three or four basal antennal joints, and anterior legs rufotestaceous, front femora darker above; middle metatarsi basally whitish, hind femora and tibiæ slightly rufescent, their tarsi red; the femoral teeth white. Stigma and nervures red-brown.

MINDANAO, Zamboanga (*Baker*).

This species is especially distinguished by the sculpture of the mesonotum.

**DIASTEPHANUS CLAVICOXIS** sp. nov., female.

*Female*.—Frons, vertex, and occiput finely and evenly transstriate, latter basally smooth, ocellar space obliquely striate, no stronger carinæ behind posterior ocelli, posterior tubercles distinct, posterior margin of head bordered; pronotum smooth, neck somewhat elongate; mesonotum rugose, with central impression only, the others obsolete; scutellum smooth; mesopleuræ smooth and shining; metapleuræ and median segment confluent, rather coarsely punctate; petiole evenly transstriate, as long as the remaining shining segments, second basally slightly rugose; terebra shorter than body, rufescent. Hind coxæ clavate, finely and evenly transstriate, as long as the bidentate femora, tibiæ not much longer than femora, compressed to beyond middle,

femora and tibiæ transaciculate, metatarsus rather more than twice as long as the remaining joints. Radius emitted from apical fourth of the long narrow stigma, its distal section about one and a half times as long as the proximal.

Black; head dark red, frons rufescent, anterior legs light red, hind femora nigrescent, their tibiæ rufescent; middle metatarsi basally, hind femoral teeth, and hypopygium white; hind tarsi rufescent.

Length, 12 millimeters; abdomen, 7; petiole, 3.5; terebra, 10.

MINDANAO, Kolambugan (*Baker*).

Differs from *D. levis* mainly in the shape of the hind coxæ and the rufescent terebra.

**DIASTEPHANUS ALBIDENS** Kieffer, female.

*Diastephanus albidens* KIEFFER, Philip. Journ. Sci. § D 11 (1916) 407, female.

The difference between this species and my *D. flavonotatus* appears to consist chiefly in the bordered posterior margin of head, sculpture of occiput, and proportions of basal antennal joints.

**DIASTEPHANUS ALBONOTATUS** Elliott.

*Diastephanus albonotatus* ELLIOTT, Philip. Journ. Sci. 29 (1926) 526, female.

This is another of the closely allied group, differing chiefly in the proportions of the antennal joints, posterior border of head, sculpture of the median segment, and color of the abdomen. The present species has pale markings on several segments, in addition to the conspicuous white spot on third.

Length, 7 millimeters; abdomen, 4; petiole, 2; terebra, 5; band, 0.75.

MINDANAO, Dapitan. SAMAR. PANAY, northwestern part (*Baker*).

**DIASTEPHANUS FLAVONOTATUS** Elliott, female and male.

*Diastephanus flavonotatus* ELLIOTT, Entom. 52 (1919); Proc. Zool. Soc. London (1922) 826, male; G. CABALLOS, "Eos," Revista Española de Entomología 2: 146, female and male.

The female agrees in all essentials with the male, but the median segment is more lightly sculptured; the terebra is shorter than the body, white-banded.

Female, length, 6.5 to 11 millimeters; abdomen, 4.5 to 6.5; petiole, 2 to 3; terebra, 4 to 6; band, 1 to 2. Male, length, 7.5 to 10 millimeters; abdomen, 4 to 6.5; petiole, 2 to 3.

BORNEO, Sandakan. LUZON, Mount Maquiling. MINDANAO, Iligan, Kolambugan, Dapitan, Davao. SAMAR. SIBUYAN. PANAY, northwestern part. NEGROS, Cuernos Mountains (*Baker*).

**DIASTEPHANUS LEUCODONTUS** Schletterer, female and male.

*Diastephanus leucodontus* SCHLETTERER, Berl. Ent. Zeit. 33 (1889) 121; ENDERLEIN, Zool. Anz. 33 (1905) 475; ELLIOTT, Proc. Zool. Soc. London (1922) 819, female.

*Female*.—Frons and vertex more or less distinctly transrugose, occiput very short, transstriate, basally more finely, anterior tubercle wanting, three costæ behind posterior ocelli, ocellar space oblique striate, posterior margin of head simple; cheeks longer than scape, second flagellar joint half as long again as first, third rather longer than first and second together; neck elongate, finely transaciculate or almost smooth, semiannular subnitidulous; mesonotum short, with central line of punctures only, laterally rugose; scutellum smooth; mesopleuræ smooth above, finely and diffusely punctate beneath; metapleuræ more or less coarsely punctate, separated by a carina from the median segment, which is centrally smooth, laterally punctate, apically more closely; petiole finely transstriate, varies from slightly shorter to slightly longer than the remaining segments—as long in the type, shorter in specimens from Sandakan, longer in some from Kolambugan—second segment basally slightly rugose; terebra shorter than body, white-banded, the proportions of the band and the black apex vary. Hind coxæ finely and evenly transstriate, as long as the smooth, bidentate femora, their tibiæ compressed in basal two-thirds, metatarsi twice as long as the remaining joints. Radius emitted from apical fifth of stigma, its distal section twice as long as the proximal.

Black; head rufotestaceous to red, vertex darker, with a black central streak, or vertex and occiput black; pronotum sometimes brownish or rufescent; anterior legs rufotestaceous, femora and apical half of tibiæ darker; middle tibiæ sometimes basally whitish, their metatarsi basally and the hind ones entirely white; hind femoral teeth white, hypopygium yellowish; in the smallest specimens the abdomen is more or less rufescent. Stigma and nervures rufescent.

Length, 7 to 11 millimeters; abdomen, 4 to 6.5; petiole, 2 to 3; terebra, 5 to 9; band, 0.5 to 2.5.

BORNEO, Sarawak (*Schletterer*); Sandakan. MINDANAO, Kolambugan (*Baker*).

*Male*.—The male was not known to Schletterer. It agrees structurally with the female. The neck entirely smooth, the metapleuræ and median segment more reticulate punctate. In color it agrees with the female from the same locality.

Black; head rufotestaceous, frons redder, vertex red, occiput black; pronotum red, petiole and third segment rufescent; anterior legs rufotestaceous, middle tibiæ and metatarsi whitish, hind legs rufescent, their tarsi pale.

Length, 7 millimeters; abdomen, 4; petiole, 2.

MINDANAO, Kolambugan (*Baker*).

*DIASTEPHANUS PARVULUS* sp. nov., female.

*Female*.—Frons, vertex, and occiput extremely finely transstriate, frons rather elongate, two carinæ between posterior ocelli, posterior margin of head bordered, all tubercles distinct; scape as long as cheeks, second flagellar joint little longer than first, third shorter than first and second together; neck very finely transstriate, basally narrowly smooth; mesonotum short, rugose, the longitudinal rows of punctures indistinct; scutellum and mesopleuræ smooth; metapleuræ reticulate punctate, separated by a carina from the superficially, rather irregularly punctate median segment; petiole transstriate, shorter than the remaining smooth shining segments; terebra shorter than body, rufescent. Hind coxæ transstriate, as long as the smooth, bidentate femora, tibiæ as long as the femora and trochanters together, compressed slightly beyond middle, metatarsi twice as long as the remaining joints. Radius emitted from near apex of stigma, its distal section twice as long as the proximal.

Black; head and three basal antennal joints, pronotum beneath rufotestaceous, outer orbits flavescent, occiput, pronotum above, and abdomen from second segment more or less rufescent; anterior legs rufotestaceous, middle metatarsi basally and hind ones entirely white; femoral teeth concolorous with femora. Wings strongly iridescent, stigma and nervures red-brown.

Length, 6.5 millimeters; abdomen, 4; petiole, 1.5; terebra, 5.5.

BORNEO, Sandakan (*Baker*).

The whole sculpture is extremely fine.

*DIASTEPHANUS SEMIGLABER* sp. nov., female.

*Female*.—Frons, vertex, and occiput extremely finely transstriate, posterior margin of head not bordered, two carinæ between posterior ocelli, posterior tubercles subobsolete, ocellar space oblique striate; scape slightly longer than cheeks, antennæ

normal; neck elongate and slender, apically foveate, then feebly transstriate, remainder of pronotum smooth and shining; mesonotum extremely short, apically punctate, scutellum smooth; mesopleuræ large, smooth, shining, very lightly punctate beneath; metapleuræ coarsely punctate, confluent with the reticulate punctate median segment; petiole very finely transstriate, as long as the remaining smooth segments; terebra slightly longer than body, white-banded. Hind coxæ very finely and evenly transstriate, as long as the bidentate, microscopically sculptured femora, tibiæ not much longer than femora, finely transaciculate, compressed to middle, metatarsi one and a half times as long as the remaining joints. Radius emitted from apical fourth of stigma, its distal section little longer than the proximal.

Rufescent; mesonotum and scutellum black; head and base of antennæ red, vertex and occiput nigrescent, anterior legs rufous, middle tibiæ and tarsi both basally white, hind legs entirely dark rufescent. Wings hyaline, stigma and nervures black-brown.

Length, 9 to 11 millimeters; abdomen, 5.5 to 7; petiole, 2.5 to 3.5; terebra, 9 to 12; band, 2 to 3; apex, 0.75.

BORNEO, Sandakan (*Baker*).

In the smaller specimen the frons more finely subtransversely shagreened, the posterior tubercles still less developed, and the general color somewhat darker.

*DIASTEPHANUS CLAVATUS* sp. nov., male.

*Male*.—Frons, vertex, and occiput finely arcuate striate, posterior margin of head bordered, two carinæ between posterior ocelli, ocellar space oblique striate, all tubercles well developed; scape as long as cheeks, antennæ normal; neck elongate, basally finely transstriate, remainder of pronotum smooth and shining; mesonotum long with a few punctures, only the central impression basally indicated; scutellum and mesopleuræ smooth and shining, metapleuræ and median segment confluent, cribrate punctate; petiole very finely transstriate, longer than the remaining smooth segments. Hind coxæ apically very strongly clavate, basally transstriate, apically transaciculate, longer than the bidentate femora, which are dull and transaciculate, as are also the tibiæ, which are compressed in basal two-thirds, metatarsi slightly longer than the remaining joints. Radius emitted from apical fifth of the long, narrow stigma, its distal section twice as long as the proximal.

Black; head rufescent, frons apically, outer orbits, scape, and first flagellar joint flavescent; hind legs rufescent, anterior legs lighter, middle metatarsi basally white; femoral teeth red.

Length, 7.5 to 9 millimeters; abdomen, 4.5 to 5.5; petiole, 2.5 to 3.

MINDANAO, Kolambugan. BORNEO, Sandakan (*Baker*).

These specimens bear a strong resemblance to my *D. clavicornis*. The hind coxæ are even more strongly clavate, the petiole and the distal section of radius are proportionally longer but, above all, the femoral teeth are concolorous with the femora, which makes it impossible to unite the species, as such difference between the sexes is not known to exist.

DIASTEPHANUS COSTIFRONS sp. nov., female.

*Female*.—The frons is costate rather than striate; the inner costæ extend into the ocellar space on each side of the ocellus, the others follow the lower curve, ending against the eyes; vertex and occiput finely transstriate, posterior margin of head extremely finely bordered, one strong carina between posterior ocelli, posterior tubercles small, broad, and inconspicuous; scape as long as cheeks, antennæ normal; neck somewhat elongate, evenly transstriate, as is also the apical half of the semianular; mesonotum irregularly rugose, no trace of the usual longitudinal impressions; central lobe of scutellum smooth and shining, the lateral lobes dull, with microscopic sculpture; mesopleuræ smooth and shining, metapleuræ coarsely punctate, confluent with the reticulate punctate median segment; petiole finely transstriate, as long as the remaining smooth, rather dull segments; terebra rufescent, shorter than body. Hind coxæ transstriate, subclavate, about as long as the smooth bidentate femora, tibiæ longer than femora, compressed to beyond middle, metatarsi three times as long as the remaining joints. Radius emitted from apical fifth of stigma, its distal section twice as long as the proximal.

Black; head rufotestaceous, vertex and occiput red, legs rufescent, middle tibiæ and metatarsi basally white, hind tarsi red.

Length, 10 millimeters; abdomen, 6; petiole, 3; terebra, 8.

BORNEO, Sandakan (*Baker*).

The structure of the frons appears to be unique, and contrasts strongly with the fine striation of the vertex and occiput.

## NEW MUSCOIDEA FROM THE PHILIPPINES REGION

By CHARLES H. TYLER-TOWNSEND

*Of the Instituto de Parasitologia Agrícola, Lima, Peru*

This paper presents some of the results of a study of material sent me by the late Prof. Charles F. Baker.

### Genus *UROEUANTHA* novum

Genotype, *Uroeuantha longipes* sp. nov., Kolambugan, Mindanao.

Differs from *Minthomyia* as follows: Frontal profile at least  $1\frac{1}{2}$  times facial profile; clypeus nearly flush, depressed next facialia, subequilateral, length of clypeus nearly 3 times clypeal width; palpi short, stout-cylindric, bowed, not thickened at tip in male; base of antennæ rather below eye middle; male width of vertex hardly over  $\frac{1}{11}$  head width, front equilateral on hind  $\frac{2}{3}$  and then widening to  $\frac{1}{2}$  head width at base of antennæ; 2 hairlike verticals in male, inner verticals convergent; no reclinate fronto-orbitals in male; frontalia in male linelike, visible only on forward half, parafrontalia approximated over frontalia and meeting on posterior half; 3 pairs proclinate ocellars, curved, not divaricate; parafacialia narrow, nearly equilateral, not quite as wide as facialia reversed; cheeks hardly over  $\frac{1}{10}$  eye length; 1 sternopleural, 3 postsutural dorsocentrals, 3 preacrostichals but only middle one strong, no postacrostichals, 2 lateral scutellars, apical pair of scutellar bristles decussate and shorter than basal lateral scutellars, no discal scutellars; 1 bristle at base of fifth radial or third vein; fifth radial or apical cell widely open well before wing tip; third medial or hind cross vein nearer cubitus and nearly its length therefrom, long; male front legs and hind legs extraordinarily long, very slender, tarsi extremely elongate (middle legs missing); front metatarsi equal to front tibiae, hind metatarsi equal to next joint of tarsi; male fourth apparent or fifth actual abdominal segment caudate, tail as long as rest of segment; scattered long discal and terminal bristles below and on sides and tip of fourth apparent or fifth actual

abdominal segment, but only short bristles above like hairs of rest of abdomen.

**UROEUANTHA LONGIPES** sp. nov.

Length of body, 12 millimeters; length of wing, 11; 1 male, Kolambugan, Mindanao, No. 23236 (*Baker*).

Head silvery, frontalia brown, palpi very pale testaceous; plr silvery, mesoscutum silvery with a faint yellowish tinge; 4 black thoracic vittæ, inner pair of thoracic vittæ linelike before transverse suture but lost behind transverse suture in wide median black area that does not reach hind margin of postscutum and narrows some posteriorly; scutellum blackish brown, silvery on tip; abdomen yellow, with extreme base above, median vitta above and below, hind edge of second apparent or third actual abdominal segment and all of last 2 abdominal segments except front fourth of third apparent or fourth actual abdominal segment brownish black, basal fourth of last 2 abdominal segments silvery; legs dark brown, coxæ silvery; wings faintly yellowish smoky, costa stigma to wing tip slightly more marked; squamæ translucent, with straw-colored edge.

**Genus URODEXIOMIMA** novum

Genotype, *Urodexiomima uramyoides* sp. nov., Los Baños.

Differs from *Pseudodexia* as follows: Frontal profile rather flattened, but little arcuate,  $1\frac{1}{2}$  times facial profile; clypeus nearly flush, narrow, length of clypeus over twice clypeal width; facialia bare, flattened-cordlike; vibrissal axis some less than antennal axis, latter quite  $\frac{2}{3}$  head height; palpi long, slender, subcylindric, scarcely thickened at tip in male, a little thicker on distal third; base of antennæ rather below eye middle; male, third antennal joint 3 times second antennal joint, narrow, rounded at tip; arista short, scarcely longer than third antennal joint, thinly long-plumose to tip; male, width of vertex  $\frac{1}{2}$  head width, front equilateral on hind half and then widening to  $\frac{1}{2}$  head width at base of antennæ; verticals 1 in male; parafacialia bare, strongly narrowed below, as wide above as clypeal width; cheeks probably about  $\frac{1}{2}$  eye length (shrunk); 2 postintraalar and postacrostichals, 2 long lateral scutellars, long decussate apical scutellars, 1 moderately strong discal scutellar; first radial or first vein terminating very far beyond sixth radial or small cross vein, with 1 bristle at tip on one side; fifth radial or apical cell narrowly open moderately before wing tip; third medial or hind cross vein sinuate,  $\frac{2}{3}$  its length from cubitulus; squamæ

rather large, strongly widened behind, the subangular inner hind corner of squamæ produced inward; 1 median marginal on first apparent or second actual abdominal segment.

*URODEXIOMIMA URAMYOIDES* sp. nov.

Length of body, 8.5 millimeters; length of wing, 7.5; 1 male, Los Baños, Luzon (*Baker*).

Head tawny silvery; frontalia and antennæ reddish fulvous, third antennal joint largely brown; palpi fulvous; plr and mesoscutum grayish silvery; 4 thoracic vittæ, outer pair of thoracic vittæ very broad and interrupted at transverse suture, inner pair of thoracic vittæ narrow before transverse suture, all 4 subconfluent behind transverse suture in a large rich brown subrectangular marking showing some golden pollen; scutellum brown on base, pollinose on tip and hind margin; abdomen fulvous yellow, with median vitta, basal or first actual abdominal segment, hind third of first apparent or second actual abdominal segment, hind  $\frac{2}{3}$  second apparent or third actual abdominal segment, hind half of third apparent or fourth actual abdominal segment, and angular tip of fourth apparent or fifth actual abdominal segment brown; bases of intermediate segments narrowly silvery, nearly basal  $\frac{2}{3}$  of fourth apparent or fifth actual abdominal segment silvery; coxæ and femora fulvous, tibiæ little darker, tarsi blackish; wings nearly clear, squamæ glassy whitish.

Genus *SISYROPODODEXIA* novum

Genotype, *Sisyropododexia luteicornis* sp. nov., Mindanao.

Differs from *Spathidexia* as follows: Palpi length of haustellum, bowed, wide throughout; male third antennal joint 3 times second antennal joint, narrow, equilateral, rounded at tip; arista longer than antennæ, short-plumose halfway; eyes very large and long, not oblique, reaching far below oral margin level; male verticals  $\frac{1}{2}$  head width, front only faintly widening to less than  $\frac{1}{2}$  head width at base of antennæ; frontals stopping at base of antennæ, 4 or 5 in number; 2 verticals in male; 3 proclinate frontoöorbitals in male, set in middle of width and on hind half of length of parafrontalia; 1 reclinate frontoöorbital in male, set inside and in advance of hind proclinate frontoöorbitals; cheeks about  $\frac{1}{15}$  eye length; 2 postintraalars and preacrostichals; no costal spine; fifth radial or third vein bristled  $\frac{1}{2}$  to halfway to sixth radial or small cross vein; fifth radial or apical cell open a little before wing tip; third medial or hind cross vein sinuate,

not its length from cubitulus; all metatarsi exceeding following joints.

**SISYROPODODEXIA LUTEICORNIS** sp. nov.

Length of body, 10 to 11 millimeters; length of wing, 9; 3 males, Surigao and Dapitan, Mindanao, and Sibuyan (*Baker*).

Yellowish ground color; head silvery white; vertex and parafrontalia golden on inner edge and above; frontalia dark brown, antennæ bright yellow, palpi pale straw color; plr silvery, mesoscutum golden; 4 blackish thoracic vittæ, inner pair of thoracic vittæ narrow; scutellum pale yellowish or fulvous, light golden pollinose; abdomen fulvous yellow, with basal depression, median vitta and hind borders last 2 abdominal segments blackish; narrow base first 2 abdominal segments and basal half of fourth apparent or fifth actual abdominal segment silvery; legs yellow, tarsi and hind tibiæ black; wings yellowish on costa and wing veins; squamæ yellowish.

**Genus PHILIPPOFORMOSIA** novum

Genotype, *Philippoformosia splendida* sp. nov., Nueva Vizcaya.

Differs from *Tutilodexia* as follows: Facial carina not canaliculate on median line; arista micropubescent; parafacialia hairy; cheeks fully  $\frac{3}{4}$  eye length; fifth radial or apical cell widely open considerably before wing tip; hind tibiæ short-ciliate; fourth apparent or fifth actual abdominal segment with marginal row hairlike and longer than marginal row of third apparent or fourth actual abdominal segment.

**PHILIPPOFORMOSIA SPLENDIDA** sp. nov.

Length of body, 13 millimeters; length of wing, 14; 1 female, Imugan, Nueva Vizcaya (*Baker*).

Head metallic bluish green, frontalia dark brown; antennæ, clypeus, epistoma, facialia, palpi, and cheek grooves brownish testaceous; plr blackish green; mesoscutum bright green, with golden reflections; 4 violet cupreous thoracic vittæ, inner pair of thoracic vittæ black and narrow before transverse suture, all violaceous and subconfluent behind transverse suture, scutellum cupreous violet, narrow margin blackish green; abdomen golden green with some bright cupreous reflections; first apparent or second actual abdominal segment, median line and hind half of intermediate segments dark chocolate brown, venter showing green on front parts of first apparent or second actual abdominal segment; legs blackish; wings lightly tinged with yellowish

smoky, darker on wing veins, blackish on basal cells and first subcostal or humeral cross vein; squamæ pale smoky brown.

**Genus EPSEUDOCYPTERA novum**

Genotype, *Epseudocyptera epalpata* sp. nov., Mindanao.

Differs from Brauer and Bergenstamm's description of *Pseudocyptera* as follows: Palpi absent; female width of vertex  $\frac{1}{4}$  head width, front widening to fully  $\frac{3}{8}$  head width at base of antennæ; wings nearly clear; abdomen very long-oval, wider end forward; 2 sternopleurals, being the front ones, hind absent; 3 postsutural dorsocentrals, 2 postintraalar, 3 very short preacrostichals; 3 postracrostichals, 2 front ones short; 2 lateral scutellars, strong decussate apical pair of scutellar bristles, 1 very small hairlike discal scutellar; cheeks nearly  $\frac{1}{4}$  eye length; epistoma cut off just above vibrissal level, full width, strongly and suddenly warped; frontals 5, stopping at front edge of base of antennæ.

**EPSEUDOCYPTERA EPALPATA sp. nov.**

Length of body, 10 millimeters; length of wing, 7.5; 1 female, Davao, Mindanao (*Baker*).

Head silvery, frontalia brown; first antennal joint and basal half of second antennal joint brown, rest of second antennal joint subrufous, third antennal joint subfulvous; plr, mesoscutum, and scutellum silvery; 4 black thoracic vittæ, inner pair of thoracic vittæ narrower; abdomen black, intermediate segments widely silvery on bases; legs black, tibiæ subfulvous on distal half; wings faintly yellowish on costa, subfulvous on wing base, faintly blackish at wing tip; squamæ watery whitish.

**Genus PALPOCYPTERA novum**

Genotype, *Palpocyptera pulchra* sp. nov., Mindanao.

Differs from *Ocypteropsis* as follows: Frontal profile not over  $\frac{3}{8}$  facial profile, flat, but little sloped; clypeus flush, arched on median line, length of clypeus  $1\frac{1}{2}$  times clypeal width; epistoma cut short, full width, well warped; vibrissal axis equal to antennal axis, latter nearly  $\frac{3}{8}$  head height; proboscis (retracted) apparently short but slender and corneous, labella rather small; female width of vertex  $\frac{3}{18}$  head width, front widening gradually, face in middle little over  $\frac{1}{2}$  head width; 1 long strong vertical in female; frontalia gently narrowed behind, width of frontalia little over  $1\frac{1}{2}$  times width of parafrontal in middle in female;

parafacialia bare, narrow, long, nearly equilateral, little wider than widest part of facialia; 3 preacrostichals; 4 postacrostichals, front 2 weaker; 1 discal scutellar, shorter than the decussate apical scutellars; fifth radial or apical cell petiolate well before wing tip, stalk shorter than sixth radial or small cross vein; third medial or hind cross vein strongly sinuate,  $\frac{2}{3}$  its length from cubitulus; marginal row on third apparent or fourth actual abdominal segment.

**PALPOCYPTERA PULCHRA** sp. nov.

Length of body, 16.5 millimeters; length of wing, 13; 1 female, Surigao, Mindanao (*Baker*).

Shining black; head light golden pollinose, changing in oblique view to rust brown; frontalia velvety dark brown; parafrontalia shining dark brown on over hind half; palpi dark brown, tips paler; occiput gray, occipital beard pale brassy; plr, mesoscutum, and scutellum thinly silvery; 4 black thoracic vittæ, inner pair of thoracic vittæ linelike; basal third of second apparent or third actual abdominal segment and nearly basal half of third apparent or fourth actual abdominal segment deep golden pollinose; coxæ and femora pale golden pollinose on outside; tibiæ rufous except base; wings well suffused with yellow, wing veins darker; squamæ nearly concolorous, more or less glassy.

**Genus OPSOCYPTERA** novum

Genotype, *Opsocyptera optima* sp. nov., Mindanao.

Differs from *Ocypterula* as follows: Clypeus flush, narrow, long, equilateral, length of clypeus fully  $2\frac{1}{2}$  times clypeal width; epistoma full width, strongly warped, length of epistoma nearly  $\frac{1}{2}$  width of epistoma; vibrissal axis exceeding antennal axis, latter nearly head height; eyes bare, long, oblique, reaching rather below oral margin level and well below vibrissal level; female, width of vertex scarcely  $\frac{1}{2}$  head width, front widening gently to over  $\frac{1}{2}$  head width at base of antennæ; frontals 5 or 6, small, stopping even with frontalia and closely approximated to same; 2 proclinate frontoöorbitals in female, hind one very short and weak like frontals; 1 weak reclinate frontoöorbital in female; ocellars 1, weak, proclinate, and 1, weak, divaricate behind ocelli, also occipitocentrals behind latter; parafacialia bare, equilateral, width of parafacial a little less than clypeal width; cheeks  $\frac{1}{2}$  eye length; 2 sternopleurals; 2 lateral scutellars, both long and equal; strong decussate apical pair of

scutellar bristles, shorter than lateral scutellars; first medial or apical cross vein strongly sinuate; short stump of vein at cubitus; female abdomen long and narrow, equilateral, length of abdomen over twice length of thorax, 5 abdominal segments seen from above but first very short; fourth apparent or fifth actual abdominal segment with marginal row of 6 but median marginal pair set so far forward as to appear discal.

**OPSOCYPTERA OPTIMA** sp. nov.

Length of body, 8 to 9 millimeters; length of wing, 6 to 6.75; 2 females, Dapitan and Kolambugan, Mindanao, No. 23258 (*Baker*).

Head silvery, parafrontalia faintly brassy; frontalia dark brown, antennæ blackish; plr silvery between leg grooves; meso-scutum thinly silvery, with very faint brassy tinge; 4 thoracic vittæ dark, outer pair of thoracic vittæ heavy, inner pair of thoracic vittæ very delicate and linelike; scutellum thinly silvery; abdomen rufous, with extreme base, median vitta on base, hypopygium, fourth apparent or fifth actual abdominal segment and irregular hind half of third apparent or fourth actual abdominal segment black; second apparent or third actual abdominal segment narrowly silvery on base, third apparent or fourth actual abdominal segment silvery more or less on basal two-thirds; legs black; wings yellow on broad costobasal portion, blackish on rest of wing-vein region but with light areas in fifth radial or apical cell and discal cell, wide irregular inner border nearly clear; squamæ whitish, edges narrowly tawny.

**Genus ZAMBESOIDES** novum

Genotype, *Zambesoides samarensis* sp. nov., Samar.

Differs from *Zambesa* as follows: Head wider than high, vertex well depressed below top level of eyes; vibrissal axis equal to antennal axis, latter  $\frac{3}{4}$  head height; second antennal joint elongate, third antennal joint in female hardly 3 times second antennal joint; eyes bare, oblique, reaching nearly to vibrissal level; female width of vertex hardly over  $\frac{1}{4}$  head width, front widening very gradually to scarcely  $\frac{1}{4}$  head width at base of antennæ; face in middle little over  $\frac{1}{3}$  head width; verticals 1 in female, decussate; 1 strong proclinate frontoörbital in female; frontalia gently narrowed behind, width of frontalia equal to width of parafrontal in middle; no preacrostichals, 1 weak post-acrostichal; apical pair of scutellar bristles decussate, equal

to basal lateral scutellars; sixth radial or small cross vein normal, first radial or first vein terminating opposite same; fifth radial or apical cell open twice mouth width of fifth radial or apical cell before wing tip, tip of cell elongate and narrow; cubitulus rounded obtuse angled,  $\frac{1}{3}$  width of wing from hind margin of wing; first medial or apical cross vein arcuate inward; no median discals on any abdominal segments.

**ZAMBESOIDES SAMARENSIS** sp. nov.

Length of body, 11 millimeters; length of wing, 9; 1 female, Samar (*Baker*).

Head silvery, parafrontalia more leaden silvery; frontalia dark brown; antennæ black, third antennal joint dark brown shading to subrufous on inner proximal half; palpi blackish; plr silvery, mesoscutum more leaden silvery; 4 blackish thoracic vittæ, inner pair of thoracic vittæ delicately linelike; scutellum black, faintly silvery; abdomen black, bases of intermediate segments and all of fourth apparent or fifth actual abdominal segment silvery, ventral triangles of silvery on first apparent or second actual abdominal segment and second apparent or third actual abdominal segment, whole venter of third apparent or fourth actual abdominal segment silvery; legs blackish, proximal  $\frac{3}{4}$  of femora largely pale fulvous; wings faintly smoky, slightly darker on costa from stigma to wing tip; squamæ glassy, narrow edges opaque straw color.

**Genus ANDROCYPTERA** novum

Genotype, *Androcyptera anorbitalis* sp. nov., Baguio.

Differs from *Ichneumonops* as follows: Clypeus flush, length of clypeus twice clypeal width; vibrissæ long, decussate, removed from oral margin at least laterally; third antennal joint  $1\frac{1}{2}$  times second antennal joint, narrow, rounded at tip; width of vertex, male and female, over  $\frac{1}{4}$  head width, front widening gently in female to  $\frac{1}{2}$  and in male to over  $\frac{1}{4}$  head width at base of antennæ; no proclinate frontoörbitalis nor reclinate frontoörbitalis, male and female; cheeks scarcely  $\frac{1}{4}$  eye length; 1 lateral scutellar; apical pair of scutellar bristles strong, decussate, not as long as lateral scutellars; fifth radial or apical cell long-petiolate far before wing tip, stalk over twice sixth radial or small cross vein and strongly bent upward; cubitulus rounded right angled to faintly obtuse angled,  $\frac{1}{3}$  width of wing from hind margin of wing; first medial or apical cross vein bent

in at tip to form a V with stalk of fifth radial or apical cell, in middle faintly bent in; no wrinkle at cubitulus; abdomen bottle-like, petiolate, length of abdomen twice length of thorax in male but not in female, first apparent or second actual abdominal segment strongly widened behind; 1 median marginal on first two abdominal segments, marginal row of 6 to 8 on last 2 abdominal segments.

ANDROCYPTERA ANORBITALIS sp. nov.

Length of body, 6 to 7 millimeters; length of wing, 4.5 to 6; 2 females, Baguio, Benguet, No. 5037; 2 males, Tangcolan, Bukidnon, No. 23240 (*Baker*).

Head silvery, parafrontalia faintly golden in male; frontalia and antennæ brown, base of third antennal joint lighter in female; plr and mesoscutum silvery, 2 very broad subconfluent black thoracic vittæ; scutellum and abdomen brownish black, bases of last 3 abdominal segments silvery; legs blackish, femora and coxæ silvery; wings lightly smoky in male, more dilute in female; squamæ nearly white, faintly yellowish in female at times.

Genus ALOPHOROPHASIA novum

Genotype, *Alophorophasia alata* sp. nov., Luzon.

Differs from *Xanthosyntomogaster* as follows: Epistoma long, wide, widened some below, well sprung, length of epistoma not half the length of clypeus nor equal to upper width of epistoma, latter twice width of facialia plus width of parafacial; vibrissæ strong, well differentiated; palpi stout-cylindric, length of antennæ, scarcely thickened at tip in male; second antennal joint elongate; third antennal joint in male nearly twice second antennal joint, rather narrow, rounded at tip; eyes bare, very large, not oblique, excavated behind on lower half, reaching below oral margin level but not completely hiding cheeks; frontals 11 to 12, close to frontalia, stopping at base of antennæ; parafacialia narrow, equilateral, width of parafacial  $\frac{1}{2}$  clypeal width and equal to width of facialia; cheeks  $\frac{1}{2}$  eye length in male; 3 sternopleurals, no preacrostichals, 1 lateral scutellar; cubitulus strongly rounded obtuse angled,  $\frac{1}{2}$  width of wing from hind margin of wing; third medial or hind cross vein sinuate, not its length from cubitulus; no median discs on any abdominal segments, macrochætæ extremely short and barely differentiated; median marginals, middle legs, and lateral discs on first apparent or second actual abdominal segment.

**ALOPHOROPHASIA ALATA** sp. nov.

Length of body, 10 millimeters; length of wing, 8.75; 1 male, Mount Banahao, Luzon, No. 5026 (*Baker*).

Head golden; frontalia, antennæ, and palpi blackish; occiput and cheeks silvery, occipital beard whitish; plr, 2 spots on front edge of prescutum, humeri, hind margin of prescutum and hind and lateral margins of postscutum silvery; rest of mesoscutum black, thoracic vittæ not apparent, scutellum brown to blackish; abdomen fulvous yellow, shading to dusky above and below on median line and hind half; legs deep brown, trochanters and coxæ subfulvous; wings lightly yellowish smoky; squamæ translucent, faintly smoky, squamulæ more opaque and whitish.

**Genus OCHROPHASIA** novum

Genotype, *Ochrophasia atripennis* sp. nov., Mindanao.

Differs from *Clytiomya* as follows: Length of epistoma half length of clypeus, width of epistoma half width of facialia plus width of parafacial, epistoma gently warped; facialia very wide, flattened, bare, slightly oblique to clypeal plane, as wide below as parafacialia, width of facialia  $\frac{2}{3}$  clypeal width; no differentiated vibrissæ, only short bristles of even length; palpi equal to third antennal joint, stout-clavate, bowed; female width of vertex not  $\frac{1}{2}$  head width, front widening very rapidly to  $\frac{2}{3}$  head width at base of antennæ; frontalia short, broad, nearly equilateral, anterior points spread, width of frontalia fully equal to width of parafrontal in middle, length of frontalia on median line from lunula to ocellar triangle little over twice width of frontalia; width of parafacial above equals clypeal width; apical scutellars parallel, short; fifth radial or apical cell open nearly in wing tip; cubitulus a rounded widely obtuse angle, scarcely  $\frac{1}{2}$  width of wing from hind margin of wing; female hypopygium small, ventrocaudal aspect, telescoped, normal, egg-depositing.

**OCHROPHASIA ATRIPENNIS** sp. nov.

Length of body, 11 millimeters; length of wing, 9.5; 1 female, Surigao, Mindanao (*Baker*).

Head golden, more brightly so on parafrontalia; frontalia and antennæ brown; palpi pale fulvous; uoce blackish; occipital beard brassy whitish; plr golden; mesoscutum blackish, margins fulvorufous and golden pollinose; scutellum and abdomen orange ocherous, venter paler yellow; legs orange yellow, tarsi and tibiæ blackish; wings smoky black throughout, scarcely lighter on inner edge; squamæ golden yellow.

Genus *OXYDEXIOPS* novum

Genotype, *Oxydexiops uramyoides* sp. nov., Mindanao.

Differs from *Meigenia* as follows: Frontal profile long, flattened in female and faintly arcuate in male, strongly sloped, scarcely longer than facial profile to end of epistoma; clypeus well depressed, narrowing gently upward, length of clypeus  $2\frac{1}{2}$  times clypeal width; epistoma long, full width, in clypeal plane in male and gently warped in female, length of epistoma fully half width of epistoma; vibrissæ strong, decussate, far above oral margin level; proboscis very short, stout, haustellum equals length of labella and not  $\frac{1}{4}$  head height, labella very large; palpi stout, bowed, length of haustellum, widened and flattened especially in female; base of antennæ on eye middle; arista longer than whole antennæ, thickened  $\frac{1}{4}$  to  $\frac{1}{2}$  way, micropubescent on little more than thickened part; width of vertex, male and female,  $\frac{1}{11}$  head width, front equilateral on over hind half of female and on nearly hind half of male, then widening to  $\frac{1}{2}$  head width at base of antennæ in male and somewhat less in female (head shrunken in female); 2 strong proclinate fronto-orbitals, male and female, close to frontals; width of frontalia half the width of parafrontal in middle in male, over half in female; cheeks  $\frac{1}{2}$  eye length in male,  $\frac{1}{3}$  in female; 2 sternopleurals, no discal scutellars; fifth radial or apical cell open well before wing tip; cubitus rounded right angled to slightly obtuse angled,  $\frac{1}{2}$  width of wing from hind margin of wing; first medial or apical cross vein well arcuate inward; squamæ rather long, well widened behind, inner hind corner of squamæ subangular, especially in male; legs long, in male middle legs longer than others; hind tibiæ short-ciliate on basal half or so, male and female, with a slightly stouter bristle near middle; female metatarsi equal following joints, middle metatarsi of female longer than following joints; male metatarsi not equal to following joints, middle metatarsi and tarsi of male very long.

*OXYDEXIOPS URAMYOIDES* sp. nov.

Length of body, 11 to 16 millimeters; length of wing, 9 to 10.5; 2 males, Butuan, Mindanao; 2 females, Davao, Mindanao, and Mount Banahao, Luzon, No. 23233 (*Baker*).

Head silvery, parafrontalia in male brassy on hind half; frontalia and antennæ blackish brown, second antennal joint and base of third antennal joint more or less rufous; palpi fulvous; plr silvery; mesoscutum silvery, faintly brassy; 4 blackish brown thoracic vittæ, inner pair of thoracic vittæ narrower, outer pair

of thoracic vittæ semicolonlike and confluent with inner pair of thoracic vittæ behind transverse suture in rectangular brown marking pronged behind on each side; scutellum dark brown on base, silvery on apical half; abdomen pale rufofulvous, female with first apparent or second actual abdominal segment, hind borders of last 3 abdominal segments and broken median vitta dark brown; male with depression of first apparent or second actual abdominal segment, narrow median vitta, broad hind borders of intermediate segments and all of fourth apparent or fifth actual abdominal segment except extreme base brown; light parts of abdomen thinly silvery pollinose and fourth apparent or fifth actual abdominal segment in male the same; legs brown, femora fulvous except tips of middle femora and hind femora; wings in female clear, in male faintly yellowish smoky on wing veins; squamæ glassy whitish, faintly tawny yellowish in male.

Genus **STRONGYLONEUOPSIS** novum

Genotype, *Strongyloneuopsis malayensis* sp. nov., Singapore.

Differs from *Strongyloneura* (*S. nepalana* Tyler-Townsend) as follows: Palpi flattened laterally, thin, widened apically, bristled; arista rather thinly long-plumose to tip; male, width of vertex one-ninth head width, front narrowed before ocellar triangle and then widened to over one-fourth head width at base of antennæ; female, width of vertex fully one-fifth head width, front widening gradually to one-third head width at base of antennæ; face below about half head width; parafacialia equilateral in male, narrowed some below in female, width of parafacialia equal to width of facialia; facioörbitalis represented by row of setæ; third long vein bristled one-third to halfway to small cross vein; apical cell open 3 to 4 times mouth width of fifth radial or apical cell before wing tip; cubitulus a widely rounded obtuse angle, about one-fourth wing width from hind margin of wing; male hypopygium large, caudoventral, first hypopygial segment with strong erect bristles, second hypopygial segment with weaker bristles; female hypopygium large, flattened boxlike, theca broad.

**STRONGYLONEUOPSIS MALAYENSIS** sp. nov.

Length of body, 8.5 millimeters; length of wing, 6.5. One male and one female, Singapore (*Baker 9152*).

Head silvery cinereous, frontalia brown, palpi and antennæ fulvous yellow; thorax and abdomen metallic green, thinly silvery white; three dark brown subequal thoracic vittæ,

obsolete before transverse suture of mesoscutum in male; first apparent or second actual abdominal segment, intermediate segments of abdomen except broad front corners, median vitta and hind half or less of fourth apparent or fifth actual abdominal segment brownish black, rest of tergum green to cupreous and silvery white pollinose; legs blackish, tibiae faintly reddish; wings yellowish on costa, except blackish cloud before wing tip; squamæ nearly white.

Genus *MEDINACEMYIA* novum

Genotype, *Medinacemyia sibuyana* sp. nov., Sibuyan.

Differs from *Euholidaya* as follows: Epistoma receding below from clypeal plane, nearly as long as upper width; proboscis stublike, not over one-fourth head height, haustellum not much longer than wide, labella large; base of antennæ on eye middle, antennæ separated at base; arista thickened one-fifth way, micropubescent halfway; eyes pushed slightly forward below, reaching median oral margin level; male, width of vertex nearly one-third head width, front widening very gradually to over one-third head width at base of antennæ; face below three-sevenths head width and appearing subequilateral with front at base of antennæ; frontals stopping even with frontalia and hugging edge of same, 6 strong; no outer verticals or proclinate frontoöorbitals in male, 2 reclinate frontoöorbitals in male; frontalia in male nearly equilateral, width of frontalia rather over width of parafrontal in middle; parafacialia bare, equilateral but widened suddenly above, scarcely as wide as facialia below; male cheeks scarcely one-sixth eye length; sternopleurals 2, strong, haustellum much longer; postacrostichals 4; third long vein bristled halfway to small cross vein; 1 median discal on last three abdominal segments.

*MEDINACEMYIA SIBUYANA* sp. nov.

Length of body, 8.5 millimeters; length of wing, 7. One male, Sibuyan Island.

Head tawny silvery, parafrontalia deep golden; frontalia dark brown; antennæ and palpi rufofulvous; pleura tawny silvery; mesoscutum golden, hind edge and four thoracic vittæ blackish, latter blotchlike except inner pair of thoracic vittæ—when 4 or more are present—before transverse suture of mesoscutum, all confluent behind transverse suture of mesoscutum as seen from behind; scutellum blackish on basal fourth, rust brown on next fourth, golden on posterior half; abdomen fulvous, faint median vitta and irregular hind margins of

abdominal segments brownish, basal half or so of last three abdominal segments bright golden pollinose; legs blackish; wings yellowish on costa and base; squamæ pale yellowish tawny.

Genus *PROPARATHELAIRA* novum

Genotype, *Proparathelaira plumosa* sp. nov., Luzon.

Differs from *Parathelaira* as follows: Frontal profile somewhat arcuate; epistoma cut off short, edge at most faintly warped, facialia straight, flattened oblique to clypeal plane; female, second antennal joint short, third antennal joint nearly four times second antennal joint and equilateral; arista thickly short-plumose halfway, then thinly shorter-plumose; female, width of vertex one-fifth head width, front gradually widening to one-third head width at base of antennæ; face only faintly widening from front; 2 verticals in female, inner verticals decussate; 2 proclinate frontoöorbitals in female, stronger than frontals; 1 reclinate frontoöorbital equal to frontals; 3 sternopleurals, 2 postintraalars, 1 preacrostichal, 1 postacrostichal; squamæ wide behind, inner hind corner of squamæ rather angular; metatarsi equal to following joints; no median discals on last three abdominal segments.

*PROPARATHELAIRA PLUMOSA* sp. nov.

Length of body, 8 millimeters; length of wing, 7. One female, Mount Maquiling, Luzon.

Head silvery white, frontalia dark brown; antennæ pale fulvous yellow; palpi pale straw yellow; thorax silvery, inner edge of parafacialia and mesoscutum along median line faintly golden; four black thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—narrow before transverse suture but coalesced behind transverse suture; abdomen translucent fulvorufous, third apparent or fourth actual abdominal segment, posterior half of second apparent or third actual abdominal segment, and median vitta blackish; last three abdominal segments narrowly silvery on base; legs fulvous yellow, tibiæ and tarsi blackish; wings lightly yellow; squamæ glassy yellow.

Genus *ASBELLOPSIS* novum

Genotype, *Asbellopsis luzonensis* sp. nov., Luzon.

Differs from *Sumatrodexia* as follows: Frontal profile faintly arcuate, hardly  $1\frac{1}{2}$  times facial profile; latter not receding; occipital plane in vertical; epistoma cut off at vibrissal level; facialia bare; proboscis half head height; haustellum 3 times

as long as thick; female, third antennal joint 3 times second antennal joint; female, width of vertex two-fifths head width, front widening gradually to fully half head width at base of antennæ; face in middle five-sevenths head width; frontals 6 in female; 2 long proclinate frontoörbital and 1 long divaricate reclinate frontoörbital in female; frontalia narrowed posteriorly, two-thirds width of parafrontal in middle in female; parafacialia bare, equilateral, equal to width of clypeus; no genoörbital; 1 postacrostichal; prescutum shorter than postscutum; 4 dark thoracic vittæ; costal spine strong, longer than small cross vein; apical cell widely open hardly twice mouth width of fifth radial or apical cell before wing tip, tip curved handlelike; apical cross vein strongly bowed in; hind cross vein its length from cubitus; squamæ rather small, a little widened behind, inner hind corner of squamæ subangular; abdomen oval in female; marginal row of 6 on second apparent or third actual abdominal segment; no median discals on fourth apparent or fifth actual abdominal segment.

**ASBELLOPSIS LUZONENSIS** sp. nov.

Length of body, 8.75 millimeters; length of wing, 7.75. One female, Los Baños, Luzon (*Baker 479*).

Head tawny pollinose, parafrontalia and upper occipital orbits somewhat deeper tawny; frontalia blackish brown; antennæ and palpi bright fulvous; cheek grooves reddish brown; pleura and mesoscutum cupreous to green, blue or violet in ground color, well tawny silvery pollinose; inner pair of thoracic vittæ—when 4 or more are present—narrow, outer pair of thoracic vittæ very heavy but rather even; scutellum brown, thinly pollinose; abdomen yellowish to fulvous, brown on median vitta, narrow hind margin of first apparent or second actual abdominal segment, wider hind margin of second apparent or third actual abdominal segment, nearly all of third apparent or fourth actual abdominal segment above, and sides of fourth apparent or fifth actual abdominal segment; bases of last three abdominal segments tawny silvery pollinose, more so on last two abdominal segments; legs fulvous yellowish, tibiæ more brownish, tarsi dark; wings lightly yellowish infusate; squamæ pale tawny translucent.

**Genus BARYDEXIA** novum

Genotype, *Barydextia bivittata* sp. nov., Luzon.

Differs from *Calotheresia* as follows: Head width scarcely equal to head height; length of clypeus twice width of clypeus;

facial carina high, wide; length of epistoma equal to width of epistoma; vibrissæ far above oral margin level; vibrissal axis equal to antennal axis, latter three-fifths head height; palpi subcylindric, bristled, little thickened at tip; 3 sternopleurals, 2 postacrostichals; 2 heavy wide black thoracic vittæ; no median marginals on first apparent or second actual abdominal segment, no median discals on intermediate segments of abdomen.

**EARYDEXIA BIVITTATA** sp. nov.

Length of body, 12 to 15 millimeters; length of wing, 11.5 to 14.5. Two males, Mount Banahao, Laguna Province, and Baguio, Benguet Subprovince, Luzon.

Head and thorax very pale brassy, including scutellum; frontalia black; antennæ and facial carina pale brownish fulvous, second antennal joint at times brown; palpi brown, paler on tip; thoracic vittæ equilateral, very wide, coalesced behind in black horseshoe following edge of postscutum from wing base to wing base and including base of scutellum; abdomen fulvous yellow, median vitta and hind border of last 3 abdominal segments dark brown; clypeus and fourth apparent or fifth actual abdominal segment silvery pollinose; legs black; wings smoky yellow on base and costal half, thinly infusate on rest; squamæ smoky yellowish.

**CALOTHERESIA BIVITTATA** sp. nov.

Length of body, 15 millimeters; length of wing, 12. One male, Surigao, Mindanao.

Differs from both *C. sumatrensis* and *C. formosensis* by the four thoracic vittæ of male being coalesced into two broad and even thoracic vittæ, except only that a split shows on forward half of prescutum; no preacrostichals; only 1 small median discal on intermediate segment of abdomen; pollen of upper parts pale brassy tinged, sides of body gray.

**TRICHOSTYLUM FASCIATUM** sp. nov.

Length of body, 9 to 10 millimeters; length of wing, 8 to 8.5. Four males, Butuan and Iligan, Mindanao (*Baker 12453*).

Dark brown, densely silvery pollinose; head silvery, frontalia dark brown; antennæ and palpi pale fulvous brown; cheek grooves fulvous brown in oblique view, wholly pollinose in direct view; whole mesoscutum, scutellum, and abdomen thickly deep soft silvery with faint suggestion of brassy, the dark parts being a lateral spot and three narrow thoracic vittæ on prescutum, over front half of postscutum with irregular hind

border, rather narrow base of scutellum, all of first apparent or second actual abdominal segment, second apparent or third actual abdominal segment except narrow front edge, less than hind half of third apparent or fourth actual abdominal segment and about hind third of fourth apparent or fifth actual abdominal segment; legs brown; wings whitish on base, smoky brown on middle and costa and following wing veins, irregular inner half nearly clear; squamæ whitish, concolorous with wing base.

*DOLESCHALLA MAKILINGENSIS* sp. nov.

Length of body, 11 to 13.5 millimeters; length of wing, 8 to 10. Four males, Mount Maquiling, Luzon (*Baker 1824 and 2020*).

Head dull silvery, dark brown stripe from lower border of eye to below oral margin of epistoma, parafrontalia appearing dull fulvous in oblique view; frontalia bright brown; antennæ brown, second antennal joint subfulvous to pale brownish; palpi brownish fulvous; humeri, pleura, and sides of mesoscutum silvery with slight brassy tinge, leaving two heavy irregular dark thoracic vittæ with a linelike one confluent with each on its inner side; scutellum bright brown, tip and postscutellum dull silvery pollinose; brown blotch under wing base; abdomen brown to dark brown, sides of first three abdominal segments yellow to rufofulvous on outer half or more, bases of last three abdominal segments narrowly and evenly silvery pollinose; legs brown, coxæ pollinose; wings narrowly deeply smoky blackish on costa, very dilute on rest; squamæ glassy, with faint sordid tinge.

Genus *LOPHOSIOPSIS* novum

Genotype, *Lophosiopsis costalis* sp. nov., Luzon.

Differs from *Euphania* as follows: Proboscis very short, haustellum hardly longer than thick and scarcely the length of the rather large labella; palpi slender cylindric, as long as lower border of head, projecting beyond oral margin of epistoma, faintly thickened tip in male; third antennal joint three times second antennal joint in male; eyes bare, oblique, reaching far short of vibrissal level; 1 strong proclinate frontoörbital in male; frontalia well narrowed posteriorly in male, short, distance of lunula to ocellar triangle on median line twice their anterior width, width of frontalia not twice width of parafrontal in middle; parafacialia narrowed below, equal to facialia reversed; cheeks rather over one-fourth eye length; 2 or 3 postacrostichals; 1 small separated discal scutellar; apical cell narrowly open not

far before wing tip, narrow and long-pointed, spearhead-shaped; cubitus a very wide obtuse angle, subangular, well over one-third wing width from hind margin of wing; male claws not over last tarsal joint; 1 millimeter on second apparent or third actual abdominal segment, marginal row of 6 or more on fourth apparent or fifth actual abdominal segment; actual fifth abdominal segment functioning as anal segment in male.

*LOPHOSIOPSIS COSTALIS* sp. nov.

Length of body, 8 millimeters; length of wing, 7. One male, Baguio, Benguet, Luzon.

Head silvery, parafrontalia more blackish through pollen; frontalia soft blackish brown, pruinose in oblique view; antennæ blackish; third antennal joint except extreme tip dusky fulvous inside, outer side and arista brown; palpi dark brown; occipital beard whitish; pleura silvery shading to dark with light incidence; mesoscutum, scutellum, and abdomen dark metallic greenish; mesoscutum and scutellum thinly silvery, leaving four dark thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—narrow; intermediate segments of abdomen very narrowly silvery on bases but widening out on venter, extending along median line of second apparent or third actual abdominal segment and same on venter of first apparent or second actual abdominal segment; legs black, femora and coxæ silvery; wings narrowly blackish on costa from stigma to tip of third radial or second vein, rest of costa and basal cells yellowish, otherwise nearly clear; squamæ glassy.

Genus *MAKILINGIMYIA* novum

Genotype, *Makilingimyia melanoptera* sp. nov., Luzon.

Differs from *Zambesa* (*Z. makilingensis* Tyler-Townsend) as follows: Frontal profile not so long as facial profile; oral profile very short, beveled anteriorly; clypeus slightly depressed, equilateral, narrow, fully 3 times width of clypeus; epistoma cut off slightly above vibrissal level; facialia narrow, parallel, flattened but raised some above clypeal plane, with short microsetæ halfway or less; vibrissæ very short, barely decussate, but well differentiated; vibrissal axis scarcely two-thirds antennal axis, latter hardly three-fifths head height; proboscis short, haustellum not over one-fourth head height, labella rather large; third antennal joint narrow, four times second antennal joint or more, upper edge concave in profile, widened slightly before the truncate

tip; arista length of third antennal joint, slightly thickened halfway, short pubescent; width of vertex in male one-fourth head width, in female little more, front widening to two-fifths head width at base of antennæ; face of male in middle half head width, of female two-fifths head width and same as anterior front; frontals stopping at base of antennæ, about 6, weak, front pair or two stronger; no outer verticals, male and female, inner verticals not decussate; frontalia very wide, equilateral, over four times width of parafrontal in middle; parafrontalia with sparse setæ which descend below base of antennæ; parafacialia long, equilateral, over half in male and under half in female width of clypeus; cheeks one-fourth eye length; cheek grooves pollinose; thorax wider than abdomen; 3 sternopleurals, 2 lateral scutellars, apical scutellars strong and decussate; small cross vein normal, first long vein terminating considerably beyond it; third long vein bristled only at base or exceptionally one-third way to small cross vein; apical cell very narrowly open, practically closed, a little before wing tip; cubitulus a rounded obtuse angle; apical cross vein slightly bent in; hind cross vein over half its length from cubitulus; last section of fifth long vein half hind cross vein; squamæ rounded-subovate and widened behind; hind tarsi rather short, especially in male; abdomen narrow, equilateral, of 5 abdominal segments, little over one and a half times thorax in length, truncate behind in male; no median marginals on first apparent or second actual abdominal segment, 1 median marginal on third apparent or fourth actual abdominal segment; hypopygium in female small, anal retracted, terminating in two setose papillæ with polished knob between them, as seen in profile.

**MAKILINGIMYIA MELANOPTERA** sp. nov.

Length of body, 8 to 9 millimeters; length of wing, 7 to 8. Two males and one female, Mount Maquiling, Luzon (*Baker 2023*).

Head silvery, posterior narrowed part of parafrontalia blackish, face and anterior part of parafrontalia in male golden; frontalia, antennæ, and palpi brown to blackish; occipital beard grayish; pleura silvery, mesoscutum and scutellum thinly silvery leaving two heavy wide equilateral black thoracic vittæ; abdomen dark brown or blackish, basal half of intermediate segments of abdomen and whole fourth apparent or fifth actual abdominal segment thinly silvery above, sides and venter silvery except

hind half of third apparent or fourth actual abdominal segment; legs black, femora and coxæ silvery; wings black, more dilute in female; squamæ white, with narrow blackish edge in male.

Genus *PHILIPPOLOPHOSIA* novum

Genotype, *Philippolophosia ornata* sp. nov., Panay.

Differs from *Lophosiodes* as follows: Frontal profile nearly flat, considerably sloped, three-fourths facial profile; occipital profile a little bulged on middle; vibrissal axis fully equal to antennal axis, latter three-fifths head height; female, width of vertex one-fourth head width, front widening gently and evenly to one-third head width at base of antennæ; face in middle scarcely half head width; 1 proclinate frontoörbital in female, strong, with 1 setalike just behind it; 1 weaker divaricate reclinate frontoörbital; 3 sternopleurals, 2 postintraalar, 2 weak preacrostichal bristles, 3 postacrostichals, 1 discal scutellar weaker than apical scutellars; hind cross vein hardly its length from cubitulus; metatarsi not equal to following joints; female front tarsi not widened; 1 median marginal on first apparent or second actual abdominal segment; first hypopygial segment in female subcylindric and about twice as long as wide, second hypopygial segment bifurcate with arms toothed on inside and each with a stout, blunt, convergent terminal hook.

*PHILIPPOLOPHOSIA ORNATA* sp. nov.

Length of body, 12 millimeters; length of wing, 9.75. One female, northwestern Panay.

Head tawny silvery, parafrontalia light golden, occiput golden above; frontalia fulvous brown; antennæ and palpi fulvous, third antennal joint edged with brownish; occipital beard brassy; humeri, pleura, and edges of mesoscutum light golden; disk of mesoscutum dark, thinly tawny silvery pollinose; 4 dark thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—a little narrower; scutellum fulvous, thinly light golden pollinose; abdomen subshining brown, shading to brownish fulvous or fulvous on venter; first apparent or second actual abdominal segment to third apparent or fourth actual abdominal segment thickly golden pollinose, leaving a bare wide hind border on first apparent or second actual abdominal segment, a wide triangle on posterior part of second apparent or third actual abdominal segment, narrow triangle on hind border of third apparent or fourth actual abdominal segment, while first apparent or second actual abdominal segment and second apparent or third actual

abdominal segment are largely bare on sides of venter; hypopygium rufofulvous, terminal hooks shining black; legs pale fulvous, tibiae testaceous, tarsi black; wings light yellowish, fading on irregular inner half, wing tip touched with smoky; squamæ tawny glassy.

Genus *PSEUDORECTOCERA* novum

Genotype, *Pseudorectocera albifacies* sp. nov., Mindanao. "

Differs from *Orectocera* as follows: Epistoma cut out extremely short, wide, rim flared; facialia finely short-ciliate in an irregular double row nearly to base of antennæ; vibrissæ well differentiated, below oral margin level, long enough for tips to meet; palpi long, somewhat bowed, inflated and somewhat flattened apically, bare on the flattened and widened tips in female; arista length of third antennal joint, considerably thickened two-thirds way and tapered, short-pubescent on upper side nearly to tip, second aristal joint twice as long as wide; cheeks one-fourth eye length; third long vein bristled one-third way or more to small cross vein; apical cell well open considerably before wing tip; tarsi scarcely elongate; abdomen subcylindric, somewhat widened on middle and well deepened posteriorly; 1 median marginal on first apparent or second actual abdominal segment.

*PSEUDORECTOCERA ALBIFACIES* sp. nov.

Length of body, 13 millimeters; length of wing, 10.5. One female, Dapitan, Mindanao.

Shining black; head burnished silvery, parafrontalia shading to blackish posteriorly; frontalia soft deep black, antennæ and palpi brownish black; upper central part of occiput blackish; humeri and pleura silvery; cut by brown subvertical bands between leg bases; mesoscutum thinly silvery, leaving two very heavy, regular, and approximated black thoracic vittæ; scutellum very thinly silvery; abdomen black, bases of intermediate segments of abdomen silvery, widening on sides and venter, first apparent or second actual abdominal segment showing some rust brown pollen on venter; legs black, femora and coxæ silvery on outside; wings deeply black infusate, with lighter areas in apical cell, discal cell, and on inner margin; squamæ white, subtranslucent.

Genus *ZAMBESA* Walker

The new species described below appears to agree well with the characters of the genotype of *Zambesa*; but, since no positive

assurance can yet be given on this point, its generic characters are here described.

Body elongate and narrow; head not much wider than high; frontal profile nearly straight, sloped but very prominent, hardly longer than facial profile; latter extremely receding, straight, at right angle to frontal profile or slightly greater; oral profile half length of frontal profile, slightly arcuate; occipital profile a little inflated below; clypeus moderately sunken, length of clypeus over twice width of clypeus; facial carina showing only as a faint sharp ridge on median line; epistoma full width, very short, edge scarcely warped; facialia bare, narrow, rather on edge, a few bristles next vibrissæ; vibrissæ strong, decussate, on oral margin of epistoma and on lower border of head; vibrissal axis hardly over half antennal axis, latter three-fourths head height; proboscis half head height, stout, labella very large, haustellum shorter than labella; palpi long, clavate and swollen, but not very stout, bowed, rather longer than labella; base of antennæ well above eye middle; antennæ long, reaching oral margin level, second antennal joint short, third antennal joint about six times second antennal joint and equilateral; arista long, bare, thickened not one-fourth way, basal joints short; eyes bare, somewhat oblique, cut out a little on lower hind border, not reaching vibrissal level; female width of vertex one-fourth head width, front widening faintly to one-third head width at base of antennæ, a little depressed between eyes in front view; face only slightly widened from front in female, not two-fifths head width in middle, appearing little wider than front but wider than width of eye; frontals 5, hugging edge of frontalia and stopping before base of antennæ; 2 verticals, male and female, inner verticals decussate; 2 proclinate fronto-orbitals and 1 reclinate fronto-orbital, male and female; frontalia in female equilateral, rather over width of parafrontal in middle; ocellars proclinate; parafrontalia widened anteriorly and produced, sloped  $45^{\circ}$ , practically bare; parafacialia bare, narrowed some below, no wider than facialia in middle, at  $40^{\circ}$  to clypeal plane; no facio-orbitals nor geno-orbitals; cheeks one-sixth eye length; cheek grooves small; thorax same width as abdomen, little narrower than head; 2 strong sternopleurals and postintraalars, 3 postsutural dorsocentrals, 2 or 3 short but rather strong preacrostichals, 2 fairly long postacrostichals; prescutum and postscutum about equal in length; 2 long strong lateral scutellars, no apical scutellars, usually 1 discal scutellar; wings

rather long and narrow, costal spine absent; first long vein bare, terminating little beyond wing middle; small cross vein distinctly to far basad of second subcostal or auxiliary vein termination, scarcely over 3 times its short length from costal side of third long vein origin; third long vein bristled only at base, yet the 3 or 4 bristles placed at usual distance apart reach halfway to small cross vein; apical cell short-petiolate fairly well before exact wing tip, stalk in line with third long vein and not so long as small cross vein; cubitus at obtuse angle, one-fourth wing width from hind margin of wing; apical cross vein crooked, not parallel to hind margin of wing, bent in before tip; no stump of vein at cubitus; hind cross vein strongly sinuate, much nearer cubitus, yet over its length from same; fifth long vein bare, last section not one-third preceding; squamæ small, rounded, level part subcircular; tarsi rather long; hind tibiae with short hairs and few bristles; middle metatarsi and hind metatarsi equal to following joints; front tarsi in female normal; male and female claws equal to last tarsal joint; abdomen nearly equilateral, thickening posteriorly in profile but appearing cylindric from above, twice length of thorax; basal of first actual abdominal segment showing distinctly from above and fully half length of first apparent or second actual abdominal segment, noticeably narrower than latter, so that abdomen is somewhat constricted at base; 1 strong median marginal on first 2 abdominal segments, 1 median discal on last 3 abdominal segments, marginal row on last 2 abdominal segments; hypopygium in female large, caudoventral aspect.

**ZAMBESA MAKILINGENSIS** sp. nov.

Length of body, 11 millimeters; length of wing, 9.5. Two females, Mount Maquiling (*Baker 2019*) and Los Baños, Luzon. One male, Surigao, Mindanao (*Baker 23237*), is evidently the same genus and probably the same species.

Head, pleura, and coxæ deeply silvery pollinose; frontalia dark brown, antennæ lighter brown, arista pale yellowish on thickened part; palpi fulvous to dark brown, in latter case (Los Baños) pale yellowish below and on tips; mesoscutum and scutellum thinly silvery, lateral and hind edges of both prescutum and postscutum deeply silvery, two narrow brown thoracic vittæ on prescutum with a brownish spot each side, disk of postscutum brown; abdomen brown to dark brown or blackish, venter of first apparent or second actual abdominal segment to third ap-

parent or fourth actual abdominal segment pale yellow except hind border; dorsum of basal or first actual abdominal segment and first apparent or second actual abdominal segment blackish or brown, with more or less yellowish showing on each side of first apparent or second actual abdominal segment; dorsum of second apparent or third actual abdominal segment yellow except hind border and wide median vitta; front half of third apparent or fourth actual abdominal segment yellow, except a broad median triangle; abdomen silvery pollinose on bases of all abdominal segments and whole fourth apparent or fifth actual abdominal segment; legs dark brown to blackish, femora except tips yellow, tibiae with more or less yellowish on middle; wings lightly smoky yellow, with clearer central area; squamæ watery to pearly whitish.

**RHODOGYNE PHILIPPENSIS** sp. nov.

Length of body, 7 millimeters; length of wing, 5.5. One male, Mount Maquiling, Luzon (*Baker 7154*).

Head pale golden yellow pollinose, parafrontalia and posterior half of frontalia deeper golden, viewed from before, rest of frontalia brownish fulvous; antennæ and occipital area of cheeks brown, palpi very pale fulvous; occipital beard brassy; mesoscutum, tip of scutellum, and postscutellum dull golden, rest of scutellum and over hind half of postscutum shining blackish except median spot on hind margin of latter; abdomen orange-yellow, extreme base and median spot on hind margin of first 3 abdominal segments brownish black; legs blackish brown; wings broadly fulvous yellow costobasally, blackish infusate across middle and nearly clear on tip and hind border; squamæ pale golden.

**Genus CRYPTOSPYLOSIA** novum

Genotype, *Cryptospylosia angustifrons* sp. nov., Luzon.

Differs from *Spylosia* as follows: Frontal profile equal to facial profile; clypeus moderately sunken, nearly equilateral, length of clypeus two and a half times width of clypeus; facia-lia ciliate with 9 to 11 strong bristles nearly to lowest frontals; vibrissal axis two-thirds antennal axis, latter three-fourths head height; palpi rather longer than haustellum, bowed; base of antennæ well above eye middle; third antennal joint in male five times second antennal joint, narrow, equilateral; eyes thickly long-hairy, oblique, reaching well short of vibrissal level; male width of vertex one-tenth head width, front narrowed somewhat before ocellar triangle and then, widening to

one-fifth head width at base of antennæ; face in middle two-fifths head width; 1 or 2 reclinate frontoörbitalis in male, weak; male frontalia not equal to width of parafrontal in middle; parafacialia a little narrowed below, no wider at narrowest than widest part of facialia; cheeks two-sevenths eye length; 3 sternopleurals, 2 preacrostichals, 2 postacrostichals, 3 long slim lateral scutellars, no apical scutellars; costal spine very short; no wrinkle at cubitulus; 2 median discals in file on intermediate segments of abdomen in male.

**CRYPTOSPYLOSIA ANGUSTIFRONS** sp. nov.

Length of body, 10.5 millimeters; length of wing, 9. One male, Baguio, Benguet, Luzon (*Baker 23246*).

Head gray cinereous, with faint brassy sheen on occiput, parafrontalia, and parafacialia; frontalia and antennæ brown, third antennal joint slightly ferruginous on extreme base; palpi fulvous yellow; pleura brassy ashy; mesoscutum and scutellum silvery whitish, base of scutellum and rectangle in middle of postscutum next transverse suture of mesoscutum brown; 4 black thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—somewhat narrower before transverse suture of mesoscutum and merged in a brown rectangle behind same; abdomen rufofulvous, depression of first apparent or second actual abdominal segment, median vitta, and hind borders of other abdominal segments dark brown to blackish, last two abdominal segments and base of second apparent or third actual abdominal segment thinly silvery; legs blackish, femora brownish; wings faintly yellowish on base and costa; squamæ yellowish, whitish on inner disk.

**Genus BOTRIOPSIS** novum

Genotype, *Botriopsis bakeri* sp. nov., Luzon.

Differs from *Botria* as follows: Frontal profile four-fifths facial profile; epistoma long, full width, not twice as long as wide; facialia heavy, wide, faintly bowed, oblique inside and outside crests, ciliate with strong bristles to lowest frontals; vibrissæ well above oral margin level; haustellum one-third head height, labella very large; palpi length of haustellum; width of vertex in female two-fifths head width, front widening rapidly to five-ninths head width at base of antennæ; face in middle nearly two-thirds head width; female with 1 vertical, 2 proclinate frontoörbitalis and 3 reclinate frontoörbitalis; frontalia hardly half width of parafrontal in middle; no ocellars; parafa-

cialia above equal to width of clypeus, narrowed below, setose on upper two-thirds; prescutum far shorter than postscutum; apical scutellars half length of lateral scutellars, strongly decussate; cubitulus rounded nearly right angled or faintly obtuse angled, apical cross vein well bent in at base; hind tibiæ ciliate with long and short bristles.

*BOTRIOPSIS BAKERI* sp. nov.

\* Length of body, 11 millimeters; length of wing, 10. One female, Baguio, Benguet, Luzon.

Head dull golden; frontalia and antennæ blackish, second antennal joint and base of third antennal joint rufous; palpi fulvorufous; pleura and mesoscutum dull golden; 5 blackish thoracic vittæ, median vitta narrower and reaching as far back as outer pair of thoracic vittæ, inner pair of thoracic vittæ—when 4 or more present—stopping in middle of postscutum; scutellum rufotestaceous, thinly dull golden pollinose; abdomen dull golden pollinose, first apparent or second actual abdominal segment and broad hind borders of intermediate segments of abdomen blackish, latter color giving out on venter; femora dull golden pollinose, tibiæ dull rufous, tarsi blackish; wings pale yellowish smoky on base and narrow costal margin; squamæ glassy whitish, with yellow edges.

Genus *PROPHORICHAETA* novum

Genotype, *Prophorichaeta philippina* sp. nov., Luzon.

Differs from *Phorichaeta* as follows: Vibrissal axis scarcely less than antennal axis, latter little over half head height; proboscis two-thirds head height; second antennal joint short, third antennal joint 3 times second antennal joint; 1 vertical in female, not decussate; 2 proclinate frontoöorbitals in female, strong; cheeks two-fifths eye length; 3 sternopleurals, 2 preacrostichals; third long vein bristled two-thirds to three-fourths way to small cross vein; stalk of apical cell little over small cross vein; hind cross vein somewhat nearer cubitulus; last section of fifth long vein equal to hind cross vein.

*PROPHORICHAETA PHILIPPINA* sp. nov.

Length of body, 6.5 millimeters; length of wing, 5. One female, Baguio, Benguet, Luzon.

Head and body metallic dark greenish; head silvery; frontalia brown, with bloom in oblique view; antennæ blackish, extreme base of third antennal joint faintly reddish; palpi obscure brownish; thorax very thinly silvery, mesoscutum and scutellum with

scarcely traces of pollen on disk; abdomen with last three abdominal segments thinly bluish silvery on base; legs black; wings tinged with brownish on costa and wing veins; squamæ tawny.

Genus *PHILIPPODORIA* novum

Genotype, *Philippodoria fasciata* sp. nov., Mindanao.

Differs from *Zizyphomyia* as follows: Epistoma one-fourth as long as wide; vibrissæ a little above oral margin level; palpi well thickened at tip in male; second antennal joint short; third antennal joint in male five times second antennal joint, moderately wide, equilateral, subtruncate at tip; eyes large, slightly oblique, reaching oral margin level; male, width of vertex two-sevenths head width, front equilateral on hind half and then widening very gradually to hardly one-third head width at base of antennæ; face only widening slightly from front, little over one-third head width in middle; frontals 8 in all, 3 below base of antennæ; only 1 frontal row in male; parafacialia narrowed below, half width of clypeus above and one-third width of clypeus below, microsetose above, not transversely corrugated; cheeks one-eighth eye length in male; 4 lateral scutellars; costal spine short but distinct; cubitus right angled, angular, hardly one-fifth wing width from hind margin of wing; apical cross vein deeply arcuate inward; metatarsi equal to following joints.

*PHILIPPODORIA FASCIATA* sp. nov.

Length of body, 7 millimeters; length of wing, 6. One male, Kolambugan, Mindanao.

Head silvery; parafrontalia, ocellar triangle, and upper occipital orbits light golden; frontalia and antennæ blackish; palpi fulvous; sternopleura silvery, mesopleura with more golden tinge; mesoscutum, apical half of scutellum, and less than basal half of last three abdominal segments golden pollinose including postscutellum, rest of scutellum and abdomen black; 4 black thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—shorter; legs brownish black; wings nearly clear, very faintly yellowish on costa and wing veins; squamæ whitish, faintly tinged with yellowish.

Genus *STURMIODORIA* novum

Genotype, *Sturmiodoria facialis* sp. nov., Basilan.

Differs from *Philippodoria* as follows: Clypeus scarcely depressed or but faintly so, length of clypeus twice width of cly-

peus; epistoma cut short; facialia bare, flattened and ironed practically into clypeal plane; vibrissæ on oral margin level; haustellum short and bulbous, scarcely longer than the large labella; base of antennæ little above eye middle; female, third antennal joint hardly three and a half times second antennal joint, equilateral, rather wide, subtruncate; eyes not oblique, reaching vibrissal level; female, width of vertex two-sevenths head width, front widening to two-fifths head width at base of antennæ; face nearly equilateral, four-ninths head width in middle and below; frontals 1, below base of antennæ; 2 proclinate frontoöorbitals and 3 reclinate frontoöorbitals in female; frontalia faintly widened posteriorly in female, little over half width of parafrontal in middle, with long fine hairs on edges; no ocellars; cubitulus rounded right angled; apical cross vein gently bent in before halfway point; hind cross vein not its length from cubitulus.

**STURMIODORIA FACIALIS** sp. nov.

Length of body, 9 millimeters; length of wing, 7. One female, Basilan (*Baker 11780*).

Head silvery; frontalia and antennæ brown, base of third antennal joint slightly tinged with ferruginous; palpi fulvous; pleura and mesoscutum silvery gray; 4 blackish thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—narrower; scutellum blackish on base, narrowly testaceous on tip, silvery gray pollinose; abdomen blackish, last three abdominal segments except hind borders silvery gray pollinose; legs blackish; wings nearly clear; squamæ whitish, faintly tawny, with yellow edges.

**Genus EOCARCELIOPSIS** novum

Genotype, *Eocarceliopsis bakeri* sp. nov., Mindanao.

Differs from *Hemisturmia* as follows: Clypeus narrowed upward, length of clypeus rather over twice width of clypeus; epistoma gently warped; facialia bare; vibrissal axis hardly two-thirds antennal axis; latter little over half head height; haustellum hardly one-third head height, labella nearly as long; eyes reaching far below oral margin level; male, width of vertex one-fifth head width, front equilateral on hind half and then widening to less than one-third head width at base of antennæ; face in middle two-fifths head width; 2 reclinate frontoöorbitals in male; frontalia well narrowed posteriorly, equal to width of

parafrontal in middle; ocellars strong; cheeks scarcely one-tenth eye length; cubitulus angular; no wrinkle at cubitulus; metatarsi equal to following joints, middle metatarsi exceed same; abdomen short-ovate; 1 weaker median marginal on first apparent or second actual abdominal segment, 1 strong median marginal on second apparent or third actual abdominal segment.

*EOCARCELIOPSIS BAKERI* sp. nov.

Length of body, 9 millimeters; length of wing, 7.5 Two males, Dapitan, Mindanao (*Baker 12459*).

Head dull silvery gray, parafrontalia with a very faint brassy tinge; frontalia and antennæ brown; palpi fulvous; pleura dull silvery, mesoscutum same with scarcely perceptible tinge of brassy; 4 blackish thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—very narrow before transverse suture of mesoscutum; scutellum blackish on basal half, fulvous on crescentic marginal area, thinly silvery and tawny pollinose; abdomen blackish, basal half or more of last three abdominal segments brassy silvery; legs dark brownish, tibiæ blackish; wings nearly clear, scarcely yellowish on costa; squamæ slightly yellowish tinged.

A female from the same locality is closely similar in appearance and color, but may not belong here. The eyes scarcely reach oral margin level and the cheeks are one-fifth eye length, while the front and face are much wider, front being nearly half head width at base of antennæ and face fully half head width in middle.

Genus *PSEUDOKEA* novum

Genotype, *Pseudokea neowinthemioides* sp. nov., Mindanao.

Differs from *Okeopsis* as follows: Epistoma warped; facialia flattened and ironed almost into clypeal plane, only slightly oblique, width of facialia quite twice width of parafacial; vibrissal axis a little less than antennal axis, latter two-thirds head height; arista longer than whole antennæ, slender throughout; frontals 2 below base of antennæ; verticals 1 in male, not decussate; frontalia haired, a little narrowed posteriorly, twice width of parafrontal in middle; cheeks one-seventh eye length and nearly completely inferior aspect; apical scutellars decussate, as long as middle lateral scutellars; hind tibiæ thickly ciliate with flattened bristles, without longer bristle; no median marginals on first two abdominal segments.

**PSEUDOKEA NEOWINTHEMIOIDES** sp. nov.

Length of body, 10 millimeters; length of wing, 7. One male, Cagayan, Mindanao.

Head silver gray; frontalia and antennæ brown, third antennal joint mostly paler; palpi fulvous; facialia brown; pleura and humeri silvery gray; mesoscutum thinly silvery, 4 blackish thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—narrow; scutellum fulvous, narrowly brown on base, silvery pollinose; abdomen subfulvous, dorsal depression of first apparent or second actual abdominal segment, middle of second apparent or third actual abdominal segment, middle and hind border of third apparent or fourth actual abdominal segment, and whole fourth apparent or fifth actual abdominal segment brown or blackish; over front half of intermediate segments of abdomen and narrow base of fourth apparent or fifth actual abdominal segment silvery pollinose; hypopygium fulvous, legs dark brown, tarsi more blackish; wings yellowish on base and costa; squamæ whitish, edges faintly yellow.

**Genus EUHYPOCHAETOPSIS** novum

Genotype, *Euhypochaetopsis orientalis* sp. nov., Luzon.

Differs from *Hypochaetopsis* as follows: Frontal profile only faintly curved, nearly equal to facial profile; clypeus dished, epistoma well warped; male, third antennal joint four and a half times second antennal joint, not thickened; arista strongly thickened little over one-fourth way; eyes rather thickly pilose, pushed forward below but occipital area of cheeks following close to their hind borders; male, width of vertex little over one-fifth head width, front at base of antennæ three-elevenths head width; frontals, 2 closely set below base of antennæ, and 3 or 4 above; costal spine very short and practically absent; apical cell moderately widely open; cubitulus nearly one-third wing width from hind margin of wing.

**EUHYPOCHAETOPSIS ORIENTALIS** sp. nov.

Length of body, 7 millimeters; length of wing, 7. One male, Baguio, Benguet, Luzon.

Head, pleura, and venter silvery whitish; front including frontalia, mesoscutum, scutellum, and dorsum of abdomen pale brassy pollinose; antennæ black; palpi fulvous; 4 equal, narrow, olive brown thoracic vittæ; first apparent or second actual abdominal segment and hind half or so of last three abdominal

segments obscure blackish; legs blackish, tibiæ subfulvous; wings smoky yellowish except inner border; squamæ glassy yellowish.

Genus **HYSTRICOVORIA** novum

Genotype, *Hystricovoria bakeri* sp. nov., Luzon.

Differs from *Catalinovoria* as follows: Head width one and a half times head height; frontal profile strongly arcuate, little over facial profile; occipital profile not bulged; head profile semi-circular; clypeus well sunken, narrow, over twice width of clypeus; epistoma cut short; facialia flattened-oblique; vibrissæ on oral margin level; vibrissal axis hardly two-thirds antennal axis, latter three-fifths head height; proboscis very short; haustellum small, bulblike, equal to labella; palpi short, clavate, with few bristles; male, third antennal joint two and a half times second antennal joint; eyes reaching slightly below vibrissal level; male, width of vertex one-third head width, front faintly widening to middle; face and anterior front equilateral, little over one-third head width; 4 frontals in all, 2 widely separated below base of antennæ and reaching to aristal level; 3 reclinate fronto-orbitals in male, hind divaricate and short, the other 2 strong; frontalia two-thirds width of parafrontal in middle; ocellar triangle very large, triangular, splitting frontalia one-third way; parafacialia bare, strongly narrowed below, peglike, almost pointed below; cheeks one-eighth eye length, occipital area of cheeks scarcely entering; 2 sternopleurals, no pteropleurals, 2 postintraalar; cubitulus two-fifths wing width from hind margin of wing; hind cross vein much nearer to small cross vein, nearly straight, nearly parallel to hind margin of wing and apical cross vein; last section of fifth long vein four-fifths preceding; metatarsi not equal to following joints; 1 erect median marginal on second apparent or third actual abdominal segment.

**HYSTRICOVORIA BAKERI** sp. nov.

Length of body, 5.5 millimeters; length of wing, 4. One male, Mount Maquilang, Luzon.

Head bluish silvery, frontalia brown; antennæ black, basal joints reddish yellow; palpi pale fulvous, thorax bluish silvery, 4 indistinct black thoracic vittæ, inner pair of thoracic vittæ—when 4 or more are present—narrow; abdomen shining black, bases of intermediate segments of abdomen bluish silvery; legs black; wings clear; squamæ nearly white.

Genus *ORILLIOPSIS* novum

Genotype, *Orilliopsis orientalis* sp. nov., Luzon.

Differs from *Brachymeropsis* as follows: Oral profile not long, well beveled anteriorly; clypeus narrow, length of clypeus two and a half times width of clypeus; epistoma gently curve-warped from clypeus; haustellum setose and two-thirds head height; palpi slender, subfiliform, half length of haustellum, bristled, not thickened at tip; second antennal joint short, third antennal joint three and a half times second antennal joint in female; arista thickened halfway and tapered; female, width of vertex fully one-third head width, front nearly equilateral but over one-third head width at base of antennæ; face and anterior front equilateral; frontals 3 in all; inner verticals not decussate; prescutum a little shorter than postscutum; 2 sternopleurals and 1 very weak one below; no costal spine; squamæ small, little widened, rather rounded behind; abdomen cylindric, nearly twice length of thorax, of 4 abdominal segments, intermediate segments of abdomen longer than the others.

*ORILLIOPSIS ORIENTALIS* sp. nov.

Length of body, 6.5 millimeters; length of wing, 5. One female, Mount Maquiling, Luzon.

Head silvery white, parafrontalia blackish posteriorly; frontalia dark brown; antennæ and palpi blackish; pleura silvery; mesoscutum and scutellum very thinly pollinose from side view, appearing bare shining blackish when viewed from above; 4 black thoracic vittæ faintly outlined before transverse suture of mesoscutum in oblique view; abdomen black, bases of last three abdominal segments thinly silvery; legs black; wings clear; squamæ glassy.

*BRACHYMEROPSIS LUZONENSIS* sp. nov.

Length of body, 6.5 millimeters; length of wing, 5.5. One male, Baguio, Benguet, Luzon.

Differs from *B. sumatrensis* Tyler-Townsend by the palpi being much shorter than third antennal joint, apical cell practically closed, costal spine very short, prescutum more shining, and thoracic vittæ much less distinct.

*APHRIMYOBIA JAPONICA* sp. nov.

Length of body, 7.75 millimeters; length of wing, 6.5. One female, Kobe, Japan.

Differs from *A. simillima* Tyler-Townsend by the third antennal joint being three times second antennal joint, arista

short-pubescent, width of vertex two-sevenths head width, front at base of antennæ one-third head width, ocellars differentiated but very fine and short, 1 postacrostichal, 2 preacrostichals, no discal scutellars, apical cell very narrowly open a little before wing tip, apical cross vein slightly arcuate inward, pollen of mesoscutum and scutellum silvery but very thin, second apparent or third actual abdominal segment black above except narrow front border on each side of median vitta, wings yellowish costally, squamæ nearly white. The prescutum is much shorter than the postscutum.

# DIE STAPHYLINIDEN DER PHILIPPINEN

## 24. BEITRAG ZUR INDO-MALAYISCHEN STAPHYLINIDENFAUNA

Von MAX BERNHAUER

Öff. Notar in Horn, Nied. Oesterreich

### Genus PAEDERUS Fabricius

1. Geflügelte Arten, Flügeldecken länger als der Halsschild..... 2.  
Ungeflügelte Arten, Flügeldecken viel kürzer als der Halsschild..... 4.
2. Hinterleib einfarbig bläulich schwarz, Halsschild rotgelb, der übrige Körper blau, Beine schwarz. LUZON, Provinz Mountain, Trinidad (Banks); Baguio (Baker): Provinz Rizal, Montalban Gorge (Banks)..... P. philippinus Bernhauer.  
Hinterleib rötlichgelb mit schwarzer Spitze..... 3.
3. Kopf so lang als breit, weitläufig punktiert, Flügeldecken sehr fein und spärlich punktiert. LUZON, Manila (Banks): Provinz Laguna, Los Baños, Mount Maquiling (Baker); ausserdem von den Sunda-Inseln bekannt..... P. intermedius Boheman.  
Kopf viel länger als breit, dicht runzelig punktiert, Flügeldecken ziemlich kräftig und sehr dicht runzelig punktiert. Ziemlich glänzend, dünn gelblich behaart, Kopf und Hinterleibsspitze schwarz, die Brust pechfarben, der Halsschild, das Schildchen, die vier ersten freiliegenden Hinterleibsringe, die Wurzel der schwärzlichen Fühler, die Taster und Beine rötlichgelb, die Knie nicht gebräunt. Kopf fast von der Form eines regelmässigen Sechseckes, kräftig und ziemlich gleichmässig dicht runzelig punktiert, ziemlich matt. Fühler mässig lang, die vorletzten Glieder doppelt so lang als breit. Halsschild oblong, ziemlich schmal, glänzend, im ersten Drittel am breitesten, nach vorn gerundet, nach rückwärts geradlinig verengt, ausser der breiten, unpunktirten Mittelzone mässig fein und ziemlich weitläufig punktiert. Flügeldecken viel länger als der Halsschild, viel länger als zusammen breit, mässig glänzend. Hinterleib fein und wenig dicht, am siebenten Tergit dichter und feiner punktiert. Länge, 7 Millimeter. SAMAR, Catbalogan (Böttcher)..... P. samarensis sp. nov.
4. Kopf und Halsschild stark metallisch glänzend blaugrün bis messingfarben, der übrige Körper schwarz, die Wurzel des achten Tergites gelb, die Fühler schwarz, die zwei ersten Glieder, die Wurzel des dritten und das Endglied rötlichgelb, die Taster rötlichgelb mit geschwärzter Spitze des vorletzten Kiefertastergliedes, die Beine schwarz, die äusserste Wurzel der Schenkel, bei var. *lividipes* die Basalhälfte der Schenkel rötlichgelb. Kopf kurz elliptisch innerhalb der Fühlerhöcker mit je einem starken Eindruck, glänzend glatt, neben den Augen mit einigen ungleich grossen Punkten, auf der hinteren Hälfte mit wenigen weiteren sehr feinen Punkten. Fühler dünn und lang, die vorletzten Glieder dreimal so lang als breit.

Halsschild hoch gewölbt, kurz eiförmig mit zwei etwas unregelmässigen Rückenreihen, sonst nur gegen die Vorderecken mit wenigen sehr feinen Pünktchen. Flügeldecken nur ein Drittel so lang als der Halsschild, an der Naht, kürzer als am Hinterrande breit, matt chagriniert, mit einigen seichten Punkten, vor der Basis mit einem mehr oder minder tiefen und grossen Eindruck. Hinterleib chagriniert, jedoch ziemlich glänzend, fein und spärlich punktiert. Die Seiten des Körpers mit mässig langen, schwarzen Borsten besetzt. Länge, 12 bis 13 Millimeter. Beim Mann ist das sechste Sternit der ganzen Länge nach schmal ausgeschnitten, die Seiten des Ausschnittes parallelseitig, dessen Spitze verrundet. LUZON, Provinz Mountain, Mount Polis und Pauai (Haight's place) (Böttcher).

*P. semiviridis* sp. nov.

- Kopf und Halsschild nicht metallisch glänzend..... 5.  
 5. Kopf schwarz ..... 6.  
 Kopf rötlichgelb ..... 9.  
 6. Flügeldecken glänzend, nicht chagriniert, fein aber scharf punktiert, pechschwarz, glänzend, spärlich graugelb behaart, die Flügeldecken schwarzblau, die Taster und die ganzen Beine sowie die Wurzel und Spitze der gebräunten Fühler rötlichgelb. Kopf rundlich, fast so breit als der Halsschild, spärlich und unregelmässig punktiert. Fühler mässig lang, die vorletzten Glieder kaum doppelt so breit als lang. Halsschild eiförmig, gewölbt, etwas breiter als die Flügeldecken, mit zwei mässig feinen Rückenreihen, seitlich spärlich und unregelmässig punktiert. Flügeldecken nach rückwärts erweitert, schmal, an der Naht fast um die Hälfte länger als breit, vor der Basis eingedrückt, deutlich und ziemlich dicht punktiert. Hinterleib fein und sehr spärlich punktiert. Länge, 6,5 Millimeter. LUZON, Provinz Mountain, Trinidad (Böttcher). Ein einziges Stück.

*P. bang-haasi* sp. nov.

- Flügeldecken matt chagriniert, nicht oder nur undeutlich punktiert.... 7.  
 7. Halsschild oblong, an den Seiten nur mässig erweitert, wenig breiter als die Flügeldecken, Mittel- und Hinterschenkel an der Spitze breit geschwärzt. PALAWAN, Binaluan. LUZON, Provinz Mountain, Mount Polis (Böttcher)..... *P. lativentris* Wendeler.  
 Halsschild viel kürzer, an den Seiten stark erweitert, mindestens um die Hälfte breiter als die Flügeldecken, die Schenkel nicht oder nur wenig angedunkelt..... 8.  
 8. Flügeldecken und Hinterleib dunkel schwarzblau, erstere ganz matt, Halsschild doppelt so breit als die Flügeldecken. Der Körper ist schwarz, die Taster, Beine, und Fühler rötlichgelb, letztere mit geschwärtzten mittleren Gliedern, die Knie der Mittel- und Hinterbeine schwach gebräunt. Kopf viel schmäler als der Halsschild, sechseckig, etwas länger als breit, nach rückwärts geradlinig verengt, die Augen vor der Mitte gelegen, die Oberfläche mit wenigen feinen Punkten. Fühler gestreckt, die vorletzten Glieder doppelt so lang als breit. Halsschild mächtig entwickelt, kugelig gewölbt, um ein Viertel breiter als lang, vor der Mitte am breitesten, nach vorn und rückwärts gleichmässig gerundet verengt, auf der Oberfläche unpunktirt, spiegelblank. Flügeldecken halb so breit und ein Drittel so lang

als der Halsschild, nach rückwärts erweitert, an der Naht so lang als am Hinterrande breit, matt chagriniert und mit wenigen seichten Punkten besetzt, vor der Mitte stark quer eingedrückt. Hinterleib quer gestrichelt chagriniert, aber doch ziemlich glänzend, nach rückwärts stark erweitert, einzeln punktiert. Länge, 7 Millimeter. LUZON, Provinz Nueva Vizcaya, Imugan (Böttcher). Ein einzelnes Stück.

*P. grandicollis* sp. nov.

Flügeldecken und Hinterleib schwarz, erstere weniger dicht chagriniert, deutlich etwas glänzend. Kopf etwas kürzer und breiter, nach rückwärts sanft gerundet verengt. Fühler fehlend. Halsschild etwas länger, weniger breit und weniger gewölbt, nur um die Hälfte breiter als die Flügeldecken, diese etwas breiter. Länge, etwas über 7 Millimeter. MINDANAO, Provinz Zamboanga, Dapitan (Baker). Ich besitze von dieser Art nur ein einziges Exemplar.

*P. bakerianus* sp. nov.

9. Halsschild dunkel, kugelig. Pechbraun, der Halsschild dunkler, der Kopf rötlichgelb, bisweilen seitlich mit einem dunklen Längswisch, die drei ersten freiliegenden Hinterleibsringe heller braun, das vierte freiliegende (sechste Tergit) und die schmale Wurzel der folgenden Tergite und die korrespondierenden Teile der Sternite rötlichgelb, die Taster und Beine, sowie die Wurzel und die Spitze der sonst geschwärtzten Fühler blass rötlichgelb, die Knie ziemlich breit gebraunt. Kopf kurz elliptisch, schmaler als der Halsschild, nur ganz vereinzelt punktiert. Fühler sehr gestreckt, dünn, die vorletzten Glieder dreimal so lang als breit. Halsschild beim Mann fast kugelig, nur wenig länger als breit, beim Weib viel schmaler und länger, nur um die Hälfte breiter als die Flügeldecken, vor der Mitte am breitesten, mit wenigen Punkten besetzt. Flügeldecken schmal, beim Mann nur halb so breit als der Halsschild, bei beiden Geschlechtern halb so lang als dieser, ziemlich matt chagriniert, einzeln und undeutlich körnig punktiert, vor der Mitte quer eingedrückt, im übrigen sehr uneben. Hinterleib nach rückwärts etwas erweitert, ziemlich kräftig und spärlich punktiert, ziemlich glänzend. Der Körper ist mit zahlreichen langen, schwarzen Borsten besetzt. Länge, 7 bis 9 Millimeter. Beim Mann ist das sechste Sternit schmal und gleichbreit, der ganzen Länge nach ausgeschnitten. LUZON, Provinz Nueva Vizcaya, Imugan (Böttcher).

*P. flaviceps* sp. nov.

Halsschild rötlichgelb, eiförmig. Von dem vorigen durch Färbung, längeren Halsschild, kürzere viel dichter skulptierte Flügeldecken verschieden. Der Körper ist blassgelb, die Hinterleibsspitze und die Knie breit schwärzlich. Der Halsschild ist um die Hälfte länger als breit, die Flügeldecken matt chagriniert, noch unebener als beim vorigen, mit zahlreichen, Borsten tragenden Körnchen besetzt. Ich war fast versucht, diese Art nur für ein unreifes Stück des *flaviceps* zu halten. Da jedoch die dunkle Färbung der Schenkel sich viel weiter, bis über die Mitte erstreckt, was bei einem unausgefärbten Exemplar gewiss nicht der Fall wäre, bin ich der Meinung, dass wir es hier mit einer von *flaviceps* verschiedenen Art zu tun haben. Länge, 6,2 Millimeter (bei eingezogenem Hinterleib). LUZON, Provinz Mountain, Balbalan (Böttcher).

*P. lividus* sp. nov.

# PHILIPPINE SURGEON FISHES AND MOORISH IDOLS

By ALBERT W. HERRE

*Chief, Division of Fisheries, Bureau of Science, Manila*

SIXTEEN PLATES AND TWO TEXT FIGURES

## ACANTHURIDÆ

### SURGEON FISHES

Body more or less oblong or ovoid, usually elevated, and much compressed laterally, the skin more or less leathery and covered with small to minute, more or less shagreenlike scales; the tail is armed on each side with one to several acute movable spines, or fixed knives or sharp-keeled bony plates, or these may be reduced to mere tubercles; in most the spines or knifelike plates form very efficient cutting weapons. Mouth small to very small, often placed very low, terminal or inferior, each jaw with a single row of fixed or movable incisors; vomer and palatines toothless; premaxillaries slightly movable but not protractile, the short maxillary closely united to premaxillary; gill rakers obsolete; pseudobranchiæ large; gills 4, a slit behind the fourth; gill membranes attached to isthmus, the openings restricted to the sides; dorsal fin single, usually with strong spines, the rayed portion longer than the spinous part; anal fin like the soft dorsal; ventrals thoracic, I-5 or I-3; the intestinal canal long, often much convoluted, pyloric cæca present; air bladder large, forked posteriorly; vertebræ  $9 + 13 = 22$ . The pelvic bones long, narrow, curved, closely connected, evident through the skin.

Herbivorous shore fishes, some representatives occurring in all tropical seas, mostly small to medium in size, a few kinds reaching a length of about two-thirds of a meter. All of them are edible and some are excellent eating when properly prepared. Mostly they are dull-colored, brown or blackish fishes, but a few are gaudily striped or marked or brilliantly decorated; some kinds are notable for their singular or fantastic appearance.

The young of these fishes present an entirely different appearance in their earlier stages, and a number of kinds were described under the name *Acronurus*, a genus created for these

larval forms. In the very young the body is proportionately shorter and more or less orbiculate or disklike; there are no scales, but the skin is corrugated with numerous transverse vertical striæ or folds, the opercles and breast silvery. As yet no one has made sufficiently extensive studies of the larval development and *Acronurus* stages of these fishes to be able to say positively to what species they belong, except in a very few cases.

Japanese fishermen catch them by the *muro ami* net method, sometimes a single haul netting as much as 2,000 kilograms. The surgeon fishes occur in schools about submerged reefs, at moderate depths, coming into shoal water to feed. Comparatively few are caught by the fishing methods of the Christian Filipinos. I am greatly indebted to Mr. T. Tamaki and his associates, Japanese fishermen operating from Manila southward in the Visayas, for many fine specimens otherwise unobtainable.

Surgeon fishes are excellent food fishes. The flesh is firm without being hard, is flaky, and of very good flavor. Few Americans or Europeans appreciate these fine fishes, and the well-to-do Tagalogs are ignorant of their good qualities. They therefore bring a very low price and are bought by the poorest people. Many much poorer fish sell for much more. They can be cooked with or without the skin, but it should always be removed before the fish is served.

A good-sized surgeon or nose fish cooked as follows is a dish worthy of any occasion:

1 onion, 1 green pepper, 1 ripe tomato. Chop fine, add 1 teaspoonful salt and  $\frac{1}{2}$  teaspoonful white pepper. Add 1 cup water, 2 tablespoonfuls butter, Crisco, or other fat, 1 tablespoonful of flour.

Clean and skin the fish, remove head and gills. Lay in pan and place dressing on top. Bake twenty-five minutes in a hot oven, or thirty minutes if the fish is a very large one. Slip from baking pan upon a hot platter without disturbing the dressing, pour any gravy over it, and serve.

*Key to the Philippine genera of Acanthuridæ.*

$\alpha^1$ . A single movable spine on each side of tail.

$\beta^1$ . Dorsal spines 9, rarely 8.

$\gamma^1$ . Teeth truncate or pointed, mostly fixed, never all movable.

$\delta^1$ . Ventrals 1-5..... *Acanthurus*.

$\epsilon^1$ . Ventrals 1-3..... *Paracanthurus*.

$\zeta^1$ . Teeth elongate, setiform, freely movable, the tips dilated on one side..... *Ctenochaetus*.

$\eta^1$ . Dorsal spines 4 or 5; soft dorsal and anal high to very high.

$\theta^1$ . Each side of caudal peduncle with one or more bony plates, usually bearing a sharp knifelike keel..... *Zebrasoma*.

..... *Naso*.

## Genus ACANTHURUS Forskål

*Acanthurus* FORSKÅL, *Descrip. Anim.* (1775) 59.

*Vernacular names.*—English, lancet fish, surgeon fish, tang; Tagalog, *indangan*, *labahita*, *samaral*; Samal and Tao Sug, *indangan*, *kumay*, *salias*, *dorong*; Visayan, *indangan*, *mungit*.

Dorsal IX— (rarely VIII—) 20 to 32; anal III— (in one species II—) 20 to 29; ventral I–5.

This genus includes those Acanthuridæ in which each side of tail is armed with a sharp movable needlelike or lancetlike spine, directed forward and fitted into a groove in the caudal peduncle; the mouth is very small, each jaw with a single row of lobate or denticulate, truncate or pointed incisors which are sometimes movable, and are usually set diagonally and are more or less imbricate; the spinous part of the dorsal is less developed than the rayed portion.

Body laterally compressed, often much flattened, elongate or deep, and covered with small to minute ctenoid or spinescent scales; pseudobranchiæ well developed; branchiostegals 5; air bladder large, forked posteriorly; the intestine has several large folds; pyloric appendages; vertebræ 9 (rarely 8) + 13.

This genus, found in all tropical seas, shares with its closest relatives the possession of the characteristic sharp caudal spine, which is indeed a frightful weapon. In using it the fish strikes sideways, its lancet held erect at right angles to the body. The lancet fishes abound around coral reefs, moving about in schools and grazing upon marine algæ. Most of the species are dull-colored, uniformly brown, or marked by fine blue dots and lines, or with more or less yellow. Some however are very gaudily marked.

*Key to the Philippine species of Acanthurus.*

a<sup>1</sup>. Body and head pale, with black crossbars..... *A. triostegus*.

a<sup>2</sup>. No black crossbars.

b<sup>1</sup>. A yellow, scarlet, or black stripe or mark on shoulder or above upper angle of gill opening.

c<sup>1</sup>. A circular bluish black spot or ring behind eye above gill opening; sides with many fine blue longitudinal lines..... *A. bariene*.

c<sup>2</sup>. A longitudinal bar on shoulder.

d<sup>1</sup>. Shoulder bar black; a narrow black pointed bar from caudal spine to middle of body..... *A. gahm*.

d<sup>2</sup>. Shoulder bar orange or yellow, broadly margined with black.

*A. olivaceus*.

b<sup>2</sup>. No spot or longitudinal stripe or bar on shoulder.

e<sup>1</sup>. A whitish or bluish ring around the mouth or lower jaw.

- f<sup>1</sup>. A large naked red, yellow, or white rhombic or ovate spot on posterior part of trunk, including caudal spine..... *A. achilles*.
- f<sup>2</sup>. No large colored spot posteriorly on side of trunk.
- g<sup>1</sup>. A large crescentic pearly spot beneath eye; a white line at base of dorsal and anal, orange posteriorly and widening almost to top of last rays..... *A. aliala*.
- g<sup>2</sup>. No crescentic white, pearly, or blue spot under eye.
- h<sup>1</sup>. Caudal with a wide yellow or orange crossband on posterior margin; opercle margined by a broad black band; nostrils blue or white, conspicuous; a white spot near angle of preopercle; caudal spine black..... *A. celebicus*.
- h<sup>2</sup>. A broad bluish white band across base of caudal; caudal spine white; a wide bluish band across breast and joined by a band on each side to ring about the mouth.  
*A. leucocheilus*.
- e<sup>2</sup>. No whitish or bluish ring around mouth or lower jaw.
- i<sup>1</sup>. Sides of body with longitudinal lines or stripes.
- j<sup>1</sup>. Back and sides yellow, the belly pale; 8 to 10 horizontal or slightly oblique blue lines from head to back and caudal fin; each blue line with a broad brown band on each side; 2 or 3 curved blue lines from eye; ground color appears as broad yellow bands..... *A. lineatus*.
- j<sup>2</sup>. Body not banded and striped as above.
- k<sup>1</sup>. Body with bluish or pale longitudinal lines or with dots or spots arranged in lengthwise series.
- l<sup>1</sup>. A black spot in axil of dorsal and anal.
- m<sup>1</sup>. Uniform brown, the sides with paler or bluish dots, forming irregular longitudinal lines, occurring also on scaled part of vertical fins; no blue stripes on cheeks ..... *A. atramentatus*.
- m<sup>2</sup>. Reddish brown or dusky brown with blue longitudinal lines on sides; 7 longitudinal blue lines on sides of head, the 3 upper ones crossing snout and uniting with those on other side; a blue band across inter-orbital ..... *A. bleekeri*.
- l<sup>2</sup>. No black axillary spot on dorsal and anal. Uniform brown with a broad bright yellow or pale interocular band; many wavy blue or brown longitudinal lines on head, breast, nape, and sides; vertical fins banded with blue and yellow, or uniform brown..... *A. dussumieri*.
- k<sup>2</sup>. Body uniformly brown or blackish brown, without bluish or pale longitudinal lines or rows of dots.
- n<sup>1</sup>. A black or chocolate brown spot in axil of dorsal and anal.
- o<sup>1</sup>. Sides of head and body above pectoral base with small circular whitish or blue spots, axillary spots deep chocolate brown; 11 or 12 teeth on each side of upper jaw ..... *A. marginatus*.
- o<sup>2</sup>. No spots on sides of head and above pectoral; axillary spots black; 6 teeth on each side of upper jaw.  
*A. nigroris*.

- n°. No black axillary spot on dorsal and anal.
- p<sup>1</sup>. A more or less distinct wide pale or whitish band on base of caudal; dorsal and anal with 4 or 5 orange bands alternating with lavender or blue bands, these usually disappearing in alcohol; teeth 9 on each side; depth 1.7 to 1.9 times in length..... *A. matoides*.
- p<sup>2</sup>. No wide pale or whitish band on caudal base.
- q<sup>1</sup>. Color black; sides of head and breast blackish brown; a deep brown ring around caudal base; fins black; 8 broad rounded teeth on each side above, 8 or 9 below..... *A. mindorensis*.
- q<sup>2</sup>. Color dark purplish brown, caudal pale brownish yellow; other fins black or deep chocolate brown; teeth narrow, pointed, 10 on each side above, 12 to 14 below ..... *A. philippinus*.

**Vernacular names.**—Ilocano, *cabcabalan*; Tagalog, *ray tapis*.  
Dorsal IX–21 to 24; anal III–19 to 21.

The oblong ovoid body laterally compressed but plump, depth 1.95 to 2 times, head 3 to 3.3 times in length; anterior dorsal profile convex from origin of dorsal to the bulging interorbital, then concave to lips, or upper part of profile may be straight or nearly so, snout concave; ventral profile a uniform arch from chin to caudal peduncle; eye rather small, high up, near profile, 4 to 4.6 times in head, but larger proportionally in young specimens; snout thin, broad tipped, about 1.5 times in head; interorbital broad, rounded, bulging laterally at upper anterior margin of eye, 3 to 3.3 times in head; posterior margin of preopercle very steeply inclined, angle broadly rounded, depth

twice in head; the small terminal mouth very low down, with 7 broad, rounded or blunt, lobate teeth on each side of upper jaw, the denticulations extending laterally nearly to their base; dorsal and anal of moderate height, rounded posteriorly; dorsal spines stout, first very short but not concealed, last twice to 2.3 times in head; dorsal and anal rays equal to or slightly greater than last dorsal spine, decreasing in length at posterior angle; anal spine equals or slightly exceeds last dorsal spine; the thick caudal peduncle somewhat flattened dorsoventrally, its depth 2.87 to 3 times in head; caudal short, with slightly concave posterior margin, 3 to 3.66 times in length; caudal spine very small, half or less than half diameter of eye in length; pectoral 1.1 to 1.2 times in head; ventral broad, 1.35 to 1.55 times in head.

The color in life of specimens from Puerto Galera, Mindoro, was pale greenish above, white below, with six black transverse bands on sides, each about as wide as pupil of eye; a black longitudinal line along middle of snout; the dorsal may be uniform green, or golden may be intermingled with the green; anterior part of dorsal with a narrow black margin.

The color in alcohol varies from cream to gray brown or dark brown, snout and nape darkest; breast, belly, and underside of caudal peduncle cream color; 5 narrow vertical or curved black or blackish brown crossbands, first passing through eye and curving forward below it, second stopping behind pectoral base; a blackish brown spot or bar on base of pectoral; a median band of the same color along snout from interorbital to its tip; a brown bar or saddle, or a spot of the same color on top and side of caudal peduncle and another spot on side near lower margin, the latter spot sometimes disappearing; a dark brown line, disappearing posteriorly, separates the cream-colored under-surface from the brown of the sides; dorsal dark brown to pale brown, darkest anteriorly, or posterior marginal region may be pale or colorless; anal pale cream with a broad brown longitudinal band covering most of it; both dorsal and anal may fade to pale cream; anal dark to pale brown or whitish, with a cream colored or white margin; caudal brown to whitish; pectoral pale yellowish to colorless; ventrals white, suffused with brown, or all gray or white.

Here described from the following specimens, ranging in length from 24 to 150 millimeters.

Paraor, La Union Province, 1.

Tailon Island, 1.

Iba, Zambales Province, 2.

Nasugbu, Cavite Province, 2.

Puerto Galera, Mindoro, 2.

Calapan, Mindoro, 20.

Balabac, 3.

Tubigan, Sulu Province, 1.

Pearl Bank, Sulu Province, 1.

Guam, 5.

I have also examined specimens from Paoay, Ilocos Norte, and Nasugbu, Batangas, in the collection of the College of Agriculture.

This handsome species was recorded by Jordan and Richardson from Calayan and Fuga Islands of the Babuyan, and from Cagayancillo in the Sulu Sea. Elsewhere this fish occurs from Ceylon to Guam, and southeast in the tropical Pacific to the Marquesas. The very closely related *A. sandvicensis* (Streets) is found from the Hawaiian Islands to the offshore islands of Mexico.

*ACANTHURUS BARIENE* Lesson. Plate 1, fig. 2.

*Acanthurus bariene* LESSON, Voy. Coquille, Zool. 2 (1830) 150.

*Acanthurus nummifer* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 172; GÜNTHER, Cat. Fishes 3 (1861) 338.

Dorsal IX-26; anal III-24.

The depth of the broadly ovoid compressed body 1.94 to 2 times in its length, deepest between ventrals and anal, the depth diminishing rapidly toward caudal peduncle; nape compressed, elevated, anterior dorsal profile very strongly convex; with age the snout may become protuberant and overhang the mouth; ventral profile deeply and evenly arched from isthmus below chin to caudal peduncle; head set diagonally, 3.5 to 3.88 times in length; the eye varies much with age, 3.85 to 4.5 times in head and 2.86 to 3.93 times in the large deep snout which has its greatest bulge below level of eye and is 1.16 to 1.38 times in head; the broad and more or less elevated interorbital space 3 to 3.85 times in head; the inferior mouth projects diagonally downward, with large tumid lips; 10 teeth on each side of upper jaw, 11 in lower jaw; upper teeth broadly pointed, and denticulate back upon sides some distance; the very short first dorsal spine entirely concealed in thick skin, and all the spines slender and comparatively weak, with only their tips exposed, the last one 1.38 to 1.7 times in head; dorsal rays equal to or a fifth higher than the spines, posterior angle of fin pointed; anal resembles dorsal, third spine 2 to 2.2 times in head, anal rays as high as

last dorsal spine, posterior angle with an elongate sharp tip; pectoral and ventrals a little more or less than head; depth of caudal peduncle 2.3 to 2.6 times in head; caudal deeply lunate with very long attenuate pointed tips of about equal length, 1.9 to 1.95 times in head; caudal spine large, thick, sharp-pointed both anteriorly and behind, pale or colorless, 2.5 to 3 times in head.

Fresh specimens were brown, with many fine wavy longitudinal blue striæ on sides, golden spots and short vermiculated lines on cheeks, and a more or less circular blue-black spot behind eye above gill opening; the dorsal was golden, except the last 5 rays which were dark violet, with 4 or 5 diagonally longitudinal violet-blue lines near margin; the anal was brown like the body, violet-blue posteriorly, with 3 longitudinal blue lines on outer portion and a marginal sky blue band; both dorsal and anal with a sky blue band along base; the caudal was bluish dusky posteriorly, with golden brown spots on lobes; the pectoral was brown basally, the rest blue-black, fading into brown marginally, with a yellow transverse bar near extremity; the ventrals were brown basally, the outer two-thirds blue-black; the caudal spine was in a blue-black spot.

Color in alcohol uniformly dark brown to blackish brown, posterior half darkest, with very many fine blue longitudinal lines, or the region above pectoral may be more or less suffused with yellowish; above upper end of gill opening and directly behind eye is a circular violet-black spot, smaller than eye, and fading in the smaller specimens; vertical fins darker than body, or dorsal may be more or less yellow; below base of dorsal is a violet-black band, broadest anteriorly and tapering back to a line which disappears about halfway to caudal; above it is a light blue line running the whole length of base; there are three longitudinal blackish violet lines along margin of dorsal, the outer one broadest; the anal has a basal and a marginal violet or blue longitudinal line; caudal shows traces of a pale basal ring; upper and lower margins of caudal brown to light brown, the lobes more or less barred or spotted, the central portion darker, becoming violet-brown to violet-black posteriorly; pectoral blackish, with a lemon yellow transverse bar near outer extremity, the bar prone to disappear in alcohol; ventrals blackish violet. In life there was evidently a broad blue band on chin. The caudal spine has a blackish brown sheath in larger specimens, a white sheath in the smaller specimens.

Here described from four specimens, 218 to 280 millimeters in length; three from Ibajay, Capiz Province, Panay, and one

from Tablas. I have also studied three very fine specimens from Ambil Island, 280 to 345 millimeters in length, and one, 310 millimeters long, from Maricaban Island. I place here a specimen, 240 millimeters long, from Bantayan Island. Instead of a black shoulder spot it has a violet-black line encircling an area on the shoulder more than twice the size of eye; the caudal has a wide bluish white ring on its base, the whole central part of fin black; the caudal spine is in a deep black spot. The shoulder mark on this specimen is much like that described for *Acanthurus tennentii* Günther.

This fish is abundant on rocky reefs in the central Visayas. The species is unique and has hitherto been known only from the type specimen, collected by Garnot at Waigiou, about 1824, and described first by Lesson, later by Valenciennes. The discovery of this fish in abundance in the Philippines constitutes one more link in the chain which binds so firmly together the Moluccas, northwestern New Guinea, and the Philippines, at least so far as their reef-dwelling fishes are concerned.

**ACANTHURUS GAHM (Forskål). Plate 12, fig. 2.**

*Chaetodon gahm* FORSKÅL, Descrip. Anim. (1775) 64.

*Acanthurus gahm* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 160; RÜPPELL, Atlas Fische (1828) 58; GÜNTHER, Cat. Fishes 3 (1861) 338; Fische der Südsee 1 (1873) 113, pl. 74; WEBER, Fische, Siboga Exp. (1913) 318.

Dorsal IX-25; anal III-23 to 24.

The oblong body is deepest before anal fin, much compressed laterally, anterior profile convex to very boldly convex, snout becoming vertical or even protuberant and overhanging mouth, depth twice, head 3.5 to 3.7 times in length; the long snout varies much in contour, becoming more and more curved in age, 1.25 to 1.4 times in head; the eye varies much in size, 3.7 to 4.6 times in head, 2.9 to 3.4 times in snout; interorbital may be broad and relatively low, or elevated and more appressed, 2.8 to 2.2 times in head; posterior margin of preopercle steeply inclined, the broadly rounded angle beneath anterior margin of eye or posterior or anterior nostril, its depth 1.6 to 1.7 times in head; mouth small, low, distinctly inferior, opening obliquely downward, with 9 teeth on each side in upper jaw, the denticulations on their tips extending up the sides for half their length; 10 teeth on each side in lower jaw; first dorsal spine very short, entirely concealed, second spine almost entirely concealed by thick skin; none of the spines strong, the last one 1.77 times in head; dorsal not high, angulate posteriorly, the rays

a trifle higher than the spines; third anal spine 2.2 to 2.3 times in head; the anal is like the dorsal in shape but the rays are a little lower, and the posterior angle is more acute and longer; pectoral equal to or a little more or less than head; ventrals pointed, the first ray in old specimens elongate and with a somewhat filiform tip, equal to or a trifle shorter than head; depth of caudal peduncle 2.4 to 2.5 times in head; caudal deeply lunate, with elongate, sharp-pointed tips, the upper a little the longer, 1.95 to 2.1 times in length; the broad acutely pointed caudal spine has a short projection backward, 4.36 to 4 times in head.

A living specimen in the Bureau of Science aquarium is grayish blue, brownish gray, or dusky brownish, according to light conditions and the state of its excitement, with a broad white band at caudal base and on caudal peduncle, and a dull blue spot on nape before origin of first dorsal; a broad black bar extends back from eye above anterior half of pectoral and a very narrow, elongate, triangulate, pointed black stripe extends forward from the black caudal spine, halfway to tip of pectoral; lips bluish white, posterior margin of opercle black; dorsal yellowish orange, anal brownish orange, each with a dark blue band along base, margin of anal vivid blue; caudal pale gray in strong light, dusky slate blue in dim light, with a broad bluish white band along its posterior margin, its upper and lower margins deep blue; pectoral blackish, with a broad lemon yellow crossbar posteriorly, its posterior margin clear.

Color in alcohol deep brown to blackish brown, the vertical fins concolorous or darker, with a black longitudinal bar on shoulder, beginning a little behind eye and running back as far as above middle or posterior third of pectoral, broadest posteriorly; from the black caudal spine an elongate, narrow, black, triangulate, pointed bar extends forward halfway to pectoral; this is absent in specimens 100 millimeters or less in length; in some specimens the dorsal is more or less yellow on the basal anterior half; the dorsal has a black marginal line, the anal a narrow blue or black margin; the caudal has a posterior white margin, within which is a black crescentic bar; some large specimens show a broad white ring or crossbar on caudal base; the pectoral has a broad posterior yellow margin, fading to pale or colorless; some specimens have a white or pale spot on anterior margin of eye, and some have the body more or less yellowish above pectoral.

Here described from 10 specimens, varying in length from 92 to 210 millimeters, from the following localities:

Tablas, 1.

Bantayan, 2.

Samal Island, Davao Gulf, 1.

Basbas Island, Sulu Province, 1.

Bungau, Sulu Province, 1.

Clarendon Bay, Balabac, 4.

This species is common in the central and southern Philippines; it occurs elsewhere from the Red Sea to the Gilbert Islands and southward to Samoa, the Society, and the Paumotu Islands.

**ACANTHURUS OLIVACEUS** Bloch and Schneider. Plate 12, fig. 1.

*Acanthurus olivaceus* BLOCH and SCHNEIDER, Syst. Ichth. (1801) 213; GÜNTHER, Cat. Fishes 3 (1861) 336; Fische der Südsee 1 (1875) 113.

*Teuthis olivaceus* JORDAN and EVERMANN, Proc. U. S. Nat. Mus. 25 (1903) 358, fig. 23; Bull. U. S. Fish Comm. 23<sup>1</sup> (1903) (1905) 385, fig. 166.

*Hepatus olivaceus* JORDAN and RICHARDSON, Bull. Bur. Fisheries 27 (1907) (1908) 270.

*Acanthurus eparai* LESSON, Voy. Coquille, Zool. 2 (1830) 147; Atlas (1826) Poissons, pl. 27, fig. 1.

*Acanthurus humeralis* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 170; EYDOUX and SOULEYET, Voy. Bonite 1 (1849) 169, pl. 2.

*Harpurus paroticus* FORSTER, Descrip. Anim. ed. Lichtenstein (1844) 183.

Dorsal IX-22 to 23; anal III-21 to 23.

Body oblong ellipsoid, compressed laterally but rather thick, depth 2 to 2.3 times, head 3.5 to 3.7 times in length; the anterior dorsal profile varies from a boldly convex arc to an irregular sinuous curve which is almost vertical on front of snout; the nape and especially the snout are laterally compressed, the snout sometimes so strongly projecting as to be almost protuberant and the profile concave above eyes; snout 1.33 to 1.44 times in head; eye rather small, about 4.75 times in head and 3.3 to 3.5 times in snout; interorbital about 3.25 times in head; posterior margin of preopercle inclined at about 45°, the angle obtusely rounded, the depth 1.7 to 1.8 times in head; mouth very low, with protuberant lips, and 8 or 9 teeth on each side of upper jaw, their broad tips lobulate-denticulate and the sides denticulate for half their length; the anterior nostril has a thin low membranous tubule becoming a high flap at rear; posterior nostril much smaller, with a thin low membranous margin except at rear; first dorsal spine low, its tip not embedded in skin, last spine twice in head; dorsal rays a little higher than

the longest spine, those at posterior angle about a fifth longer and forming a long-tipped pointed angle; third anal spine 2.66 to 2.7 times in head; anal like dorsal but lower, but sometimes the long-pointed rays of posterior angle are equal to dorsal; the broad pectoral a little shorter than head; the pointed ventral three-fourths to five-sixths the length of head; depth of the stout caudal peduncle 2.6 to 2.7 in head; caudal lunate with very long, narrow, almost filiform tips, 1.7 to 2 times in length; the stout knifelike caudal spine has a long sharp posterior point, 2.6 to 2.7 times in head.

Color in life dark olive brown, with a broad, bright, deep yellow or orange bar, broadly margined with black or dark brown, beginning as a circular spot on opercle at angle and running back horizontally along side to middle of body; the dark margin of shoulder bar is broadest posteriorly and does not merge into the body color; posterior part of pectoral whitish or with a broad yellow margin, the rest of fin very dark brown; a broad milk white crescent on posterior margin of caudal, very narrowly edged with black, the elongate caudal lobes pale brown spotted with dark brown; caudal spine covered with a very dark brown sheath, its groove edged with blackish.

Color in alcohol similar, the shoulder bar often fading to pale buff or whitish and the yellow on pectoral largely disappearing; dorsal and anal much darker brown than body, or blackish.

In some fresh specimens the shoulder bar is scarlet or some shade of red.

Here described from six specimens, 165 to 230 millimeters in length, from the following localities:

Subic Bay, Olongapo, Zambales  
Province, 1.

Ambil Island, 2.

Agutaya Island, Cuyo Islands,  
2.

Jolo, Sulu Province, 1.

This very distinct species does not seem to be abundant with us, but the Japanese fishermen have recently begun to catch a good many among the Cuyo Islands. Jordan and Richardson had a specimen from Cagayancillo, in the Sulu Sea.

It is widely distributed in the Pacific Ocean, from Formosa to Tahiti. It is common in the Caroline and Hawaiian Islands. In the East Indies it is known from Celebes and the Moluccas.

*ACANTHURUS ACHILLES* Shaw. Plate 2, fig. 1.

*Acanthurus achilles* SHAW, Gen. Zool. 4 (1803) 383; CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 160; GÜNTHER, Cat. Fishes 3 (1861) 340; Fische der Südsee 1 (1873) 115, pl. 71, fig. B; STEINDACHNER, Denkschr. Akad. Wiss. Wien. 70 (1900) 493.

- Teuthis achilles* FOWLER, Proc. Acad. Nat. Sci. Phila. (1900) 513.  
*Hepatus achilles* JORDAN and EVERMANN, Bull. U. S. Fish Comm.  
23: (1903) (1905) 384, pl. 58; JORDAN and SEALE, Bull. Bur. Fish-  
eries 25 (1905) (1906) 350; STEINDACHNER, Sitzungs. Kais. Akad.  
Wiss. 115: (1906) 1393.

Dorsal IX-31; anal II-27.

Body very broadly ovoid, very much laterally compressed, greatest depth 1.5 times in length; head placed obliquely, twice in depth, three times in length, its upper profile strongly convex to below eyes; snout moderately concave, a little more than 1.4 times in head; eye high up, circular,  $2\frac{1}{2}$  times in snout,  $3\frac{1}{2}$  times in head, and 1.1 times in the slightly ridged interorbital; posterior margin of preopercle begins beneath posterior margin of eye and descends very steeply; angle of preopercle 1.76 times in head; the small mouth low, terminal, with equal jaws, and but 4 broad, blunt, irregularly lobate teeth on each side of upper jaw; dorsal and anal alike in shape, of moderate height, the dorsal spines graduated in length to the last, which is highest; first dorsal spine not concealed, 7.5 times in head, the last one 1.57 times in head; anterior dorsal rays a trifle higher than last spine, 1.5 times in head, the posterior rays rapidly shortened; second anal spine 3.75 times in head; first anal ray stout, coarse, spinelike in appearance; the middle anal rays equal the longest dorsal rays in height; caudal peduncle much compressed laterally, its depth 2.72 times in head; caudal lunate, with elongate tips, the upper the longer, its length 1.2 times head; pectoral a tenth longer than head; the pointed ventral 1.2 times in length of head; caudal spine needle-pointed, a little shorter than eye.

Color in alcohol uniform chocolate brown, with a large ovate or rhombic naked white spot on posterior part of trunk, including caudal spine; a blue line at base of dorsal rays; above it is a wider tan or pale brown stripe, widest posteriorly, and a similar one at base of anal rays; a blue line from one angle of mouth to the other, encircling chin; the membranous posterior flap of opercle creamy white; basal portion of caudal blackish brown, then pale brown, then a blackish brown crescent followed by a broad marginal whitish crescent; outer margin of ventral blue, rest of fin blackish brown.

Here described from a specimen, 92 millimeters long, from Guam. In life this is a brilliantly colored fish. The patch on the side is bright scarlet or orange. The submarginal crescent on caudal is of the same color, and the anal stripe and upper stripe on dorsal base are likewise scarlet or orange.

This beautiful fish ranges from the China Sea to Hawaii and Samoa. It reaches a length of 230 millimeters.

I have seen no specimen from the Philippines, but there is no question of its occurrence here.

*ACANTHURUS ALIALA* Lesson. Plate 2, fig. 2.

*Acanthurus aliala* LESSON, Voy. Coquille, Zool. 2 (1830) 150.

\* *Hepatus aliala* JORDAN and SEALE, Bull. Bur. Fisheries 25 (1905) (1906) 350.

*Acanthurus glaucopareius* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 139; KITTLITZ, Mus. Senckenb. 1 (1834) 192, pl. 13, fig. 3; BLEEKER, Acta Soc. Sci. Indo-Neerl. 1 (1856) Beschriev. Vischsoorten Amboina, 47; GÜNTHER, Cat. Fishes 3 (1861) 339; Fische der Südsee 1 (1873) 114, pl. 71, fig. A.

Dorsal IX—28 or 29; anal III—25 or 26.

Depth of the short, strongly compressed, ovate body 1.7 to 1.76 times, head 3.4 to 3.6 times in length; anterior dorsal profile strongly convex from origin of dorsal to below eye, then concave to tip of snout; head small, very oblique, its length twice in depth; the large circular eye 2.75 to 2.9 times in head, 2 to 2.16 times in snout, which is much compressed laterally and 1.25 to 1.35 times in head; the broad, rounded, projecting interorbital equals eye; posterior margin of preopercle very steeply inclined, the angle broadly rounded with no perceptible lower limb, its depth 1.7 to 1.8 times in head; mouth very small, downward projecting, with 5 short broad teeth on each side of upper jaw, their truncate margin lobate denticulate; dorsal and anal rather low, rounded posteriorly, the very short first dorsal spine not concealed; dorsal spines moderately strong, the last one about two-thirds as long as head, anterior and middle dorsal rays about the same height; third anal spine and anal rays a little lower than dorsal rays; pectoral a little longer than head; ventrals short with a broad rounded tip, 1.33 to 1.5 times in head; depth of the short thick caudal peduncle 2.35 to 2.5 times in head; the short broad caudal 3.25 to 3.3 times in length, its posterior margin almost truncate or gently concave, without elongate marginal lobes; the knifelike caudal spine almost equal to eye, with a short projecting posterior point.

Color in alcohol purplish or brownish black, with a large crescentic or subcrescentic violet pearly spot under and anterior to eye; a pearly or bluish pearly ring around mouth, not continuous above; base of dorsal and anal each with a white line which broadens into a wide orange bar posteriorly, extending

nearly to top of last rays; remainder of vertical fins purplish black; caudal pale with a yellow crossbar posteriorly, the hind margin of which is a black line, and beyond this a broad terminal purplish brown band; pectoral blackish; ventrals black, the outer margin a blue line; caudal spine greenish, with a whitish sheath.

Here described from two specimens, 119 and 120 millimeters long, collected on the reef at New Washington, Capiz Province, Panay.

This easily recognized species occurs from the Moluccas to the islands off the western coast of Mexico. It ranges north to Guam and southeast to the Society Islands.

*Acanthurus celebicus* BLEEKER, Nat. Tijds. Ned. Ind. 3 (1852) 761;  
GÜNTHER, Cat. Fishes 3 (1861) 339; Fische der Südsee 1 (1875)  
115, pl. 73, fig. B.

Dorsal VIII-27; anal III-25.

The ovoid body much compressed laterally, greatest depth just before anal, 1.77 times in length; the obliquely placed head 3.48 times in length; anterior dorsal profile strongly convex from dorsal to lower level of eye, then concave to tip of snout; the elongate, depressed, pointed snout 4.39 times in head; eye near profile line, 3.6 times in head and almost 3 times in snout; interorbital broad, low, 2.9 times in head, a fourth wider than eye; posterior edge of preopercle inclined about 45°, the angle rounded, obtuse, the depth 1.8 times in head, 1.43 times in snout; mouth small, low, jaws protuberant, 7 obliquely set and laterally imbricate teeth on each side of upper jaw, their round pointed tips denticulate back for about half their length; in lower jaw are 8 larger, broader teeth similarly arranged, their tips wide and irregularly denticulate; dorsal spines short, moderately stout, tip of first one visible, the last one about 5 times in length and almost 1.5 times in head; the dorsal rays are higher and gradually increase in length posteriorly, forming a large broad point at angle, the longest rays 1.1 times in head; anal similar to dorsal in shape, the posterior angle more sharply pointed and extending farther back than the dorsal point; third anal spine 1.8 times in head; the longest anal rays a trifle shorter than the dorsal rays; the broad caudal very slightly lunate, upper margin produced posteriorly into a short sharp-pointed lobe, 2.66 times in length; caudal peduncle 2.23 times in head; caudal spine short, sharp-pointed, 5.8 times in head;

pectoral longer than head, 2.88 times in length; ventrals pointed but not elongate, 1.1 times in head.

Color in alcohol dull violet-brown, darkening toward caudal peduncle, and blackish brown on sides of head; margin of opercle purplish black; lips black, with a white ring starting on upper lip and encircling chin, its color partly suffused with violet; a white spot on preopercle, near its posterior angle; dorsal and anal violaceous black; caudal blackish centrally, with a yellowish crossband forming posterior margin; base of pectoral blackish brown, rest of fin pale, evidently yellow or reddish yellow in life; ventrals violet-brown to violet-black; the white nostrils conspicuous.

Here described from a specimen, 101 millimeters long, from Calapan, Mindoro. This rare and easily recognized species was originally described by Bleeker from a specimen collected at Macassar, Celebes. He later recorded it from Ternate, Amboina, and New Guinea. The British Museum has specimens from the Solomon Islands and Tahiti.

According to Bleeker and Günther, the fin formula is D. VIII or IX-26 or 25; anal III-24.

Since writing the above I have obtained two living specimens from Calapan, Mindoro; the larger one is shown in the colored plate. The amount and intensity of red color behind the head and about the pectoral base vary considerably, according to the light conditions and the state of excitement of the fish. A much smaller specimen is greenish gray anteriorly, the posterior third darker, becoming blackish slaty blue, or in certain lights brownish, sides of head slaty blue, a dusky patch above eye, the mouth encircled by a whitish ring, and a whitish spot near posterior angle of preopercle; the adjacent margin of breast whitish blue; nostrils in a patch of whitish blue and a spot of the same color on lower part of eye; posterior margin of opercle black; behind opercle a blackish red patch extending down to root of pectoral; dorsal and anal dull bluish slate anteriorly, darker posteriorly, the posterior half of both fins with a narrow yellow margin; posterior end of caudal peduncle and central part of caudal blackish; a band of light yellow across posterior margin of caudal, edged posteriorly with a blue line; a stripe of light yellow along lower margin and posterior half of upper margin of caudal; pectoral very pale yellow, ventral dull blue slate.

*ACANTHURUS LEUCOCHEILUS* Herre, sp. nov. Plate 12, fig. 3.

Dorsal IX-24 or 25; anal III-23.

The depth of the strongly compressed, ovate body about 2 to 2.4 times in length, the greatest depth at origin of anal; the head varies from 3.3 to 3.7 times in length; the dorsal and anterior profile of head varies considerably; it may be a steeply convex uniform curve from dorsal to below eyes, then nearly vertical to upper lip, and lips and mouth projecting, or the snout may be very convex and humplike below eyes and above mouth; the laterally appressed snout 1.3 to 1.44 times in head; eye placed high up, 3.6 to 3.9 times in head, 2.7 to 2.75 times in snout, and 1.07 to 1.28 times in the low, convex interorbital; posterior margin of preopercle begins at or below level of eye and descends very steeply, its broadly rounded angle before a perpendicular from front margin of eye, depth of preopercle 1.8 times in head; mouth very low down, with full projecting lips and protruding teeth; 9 or 10 teeth with broad lobate tips on each side of upper jaw and 10 or 11 similar teeth on each side of lower jaw; dorsal and anal of approximately equal moderate height, angulate posteriorly, first dorsal spine very small; both first and second spines concealed by a covering of thick skin, the spines increasing in length to the ninth, which is 1.68 to 1.87 times in head; the soft dorsal approximately equals the longest spine in height; first anal spine concealed, third 2.4 times in head; caudal deeply lunate with long pointed tips, 2.3 times in length, or tips elongated and ribbonlike, when the fin may be 1.5 times in length; depth of caudal peduncle 2.6 to 3.1 times in head; pectoral approximately equal to head; first ventral ray elongated, with threadlike tip, 1.1 to 1.25 times in head; the knifelike spine has a long sharp point anteriorly and a pointed posterior process, equal to or half again as long as eye.

Color in alcohol uniform blackish brown; snout just above and behind lips black; a broad bluish pearly or pearly white band encircles mouth, or may be only partially developed on upper lip; a similar wide band crosses breast from before anterior angle of gill opening to opposite side and is joined by a band on each side to the ring about mouth; a broad bluish white band encircles base of caudal; pectoral black with a bright yellow transverse bar on posterior margin, which later faded to white; dorsal, anal, and ventral black or brownish

black; central part of caudal, back to posterior margin, black, or sometimes with a bluish white lunate band near posterior margin; caudal spine white, its groove with a narrow black margin.

Here described from three specimens, 175 to 200 millimeters long, from Bantayan Island, and a specimen, 196 millimeters long, from Cebu.

A fresh specimen, 186 millimeters long, from Agutaya, one of the Cuyo Islands, was blackish brown above, deep brown elsewhere except cheeks and snout which were reddish brown; lips reddish with a broad bluish white band around mouth, and a wider blackish brown band behind it; a broad bluish white band beginning in front of anterior angle of gill opening and crossing breast to opposite side; a wide bluish white band around caudal base; dorsal and anal were dark brown, the soft dorsal with 3, the anal with 2 dark red lines near margin, alternating with bluish, and a narrow sky blue marginal line; posterior margin of both fins brick red; a deep black line below dorsal base; the caudal was very dark brown with a broad submarginal blue band, posterior edge black, upper and lower margin blue; the pectoral was blackish brown with a bright yellow transverse bar on posterior third and a broad dusky posterior margin in which the membranes were clear but the rays black; the ventrals were blackish basally and along outer margin, the rest brick red.

λευκος, white; χεῖλος, lip.

**ACANTHURUS LINEATUS** (Gmelin). Plate 14, fig. 1.

*Chaetodon lineatus* GMELIN, Syst. Nat. 1 (1789) 1246.

*Acanthurus lineatus* BLOCH and SCHNEIDER, Syst. Ichth. (1801) 214, pl. 49; CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 164; GÜNTHER, Cat. Fishes 3 (1861) 333; Fische der Südsee 1 (1873) 111, pl. 70; DAY, Fishes of India (1875) 203; WEBER, Fische Siboga Exp. (1913) 317.

*Acanthurus vittatus* BENNETT, Fishes Ceylon (1834) 2, pl. 2.

*Hepatus lineatus* JORDAN and SEALE, Bull. Bur. Fisheries 25 (1905) (1906) 351; JORDAN and RICHARDSON, Bull. Bur. Fisheries 27 (1907) (1908) 270.

*Teuthis lineatus* SEALE, Occ. Papers Bishop Museum 1 (1901) 108.

Dorsal IX-26 or 27; anal III-25 to 27.

The compressed body elongate ovoid, depth 2 or 2.1 times, head 3.7 to 3.95 times in length; anterior dorsal profile boldly convex, nape appressed and somewhat ridged, snout long, steeply declivitous, 1.3 to 1.4 times in head; eye rather small, 4 to 4.5 times in head and about 3 times in snout; the broad high inter-orbital 2.85 times in head; mouth very low, with 6 broad lobate

teeth on each side of upper jaw; first dorsal spine very short but not concealed, all the spines rather weak, the last one about 1.66 times in head; the rays about as high except those at posterior angle, which are a little more elongate; third anal spine 2.35 to 2.4 times in head, the rays a little lower than dorsal, of similar outline but more sharply angulate posteriorly; pectoral and ventral a little longer than head, ventral with an elongate pointed tip; depth of caudal peduncle twice or about twice in head; caudal spine elongate, deep and shaped like a knife blade, with a short posterior point, 1.9 to 2 times in head; caudal deeply lunate with elongate tips, equal in length or upper one slightly longer, 2.3 to 2.4 times in length.

This beautiful and vividly colored fish is the gorgeous one in a family which is mostly plain colored. The ground color is yellow, the belly blue, with eight to ten blue lines running horizontally or slightly obliquely from cheek or eye to base of caudal and the back; each blue line has a brown band on each side, as wide as the yellow stripes of the ground color between; from anterior margin of eye two similar bands curve forward down snout and around cheek to pectoral base; another goes from anterior dorsal base forward to interorbital where it joins its fellow and forms a median line on snout; some of the lines run out upon posterior part of soft dorsal, rest of fin brown with a black marginal line; 2 or 3 vertical blue lines with brown margins at base of caudal, its anterior half dark brown or blackish brown, posterior half with a broad paler lunate portion, the two colors separated by a curved blue line; pectoral brown at base, sometimes with blue lines transversely, the outer half yellow or paler; ventrals yellow or orange, with the outer part deep blue, usually fading to blackish or dark brown in alcohol; in my specimens the anal is bluish, in some blackish brown with a pale blue marginal line, the base always more or less orange.

No two specimens are exactly alike in color, and there is a wide variation in the arrangement of the stripes of color. The stripes on the body may curve up and back upon the dorsal fin, and the anterior part of the dorsal may be longitudinally barred.

Here described from the following specimens, ranging from 50 to 175 millimeters in length:

Paraoir, La Union Province, 2.  
Southern coast of Batangas  
Province, 1.

Manila, 1.  
Sibutu, Sulu Province, 1.  
Guam, 1.

Since writing the above I have received a specimen, only 35 millimeters long, from Paoay, Ilocos Norte.

Günther had a specimen labeled "Philippine Islands," and Jordan and Richardson had one from Cagayancillo. This species occurs throughout the East Indies and Polynesia to Tahiti; northward it is not known beyond Guam. In the Indian Ocean it is known from the Andamans, Ceylon, and Zanzibar.

**ACANTHURUS ATRAMENTATUS** (Jordan and Evermann). Plate 3, fig. 1.

*Teuthis atramentatus* (by misprint *utrimentatus*) JORDAN and EVERMANN, Bull. U. S. Fish Comm. 22 (1902) (1903) 198; SNYDER, Bull. U. S. Fish Comm. 22 (1902) (1903) 533; HERRE, Fishes of Marcus Island, Occ. Papers Bishop Mus. 2 (1903) 133.

*Hepatus atramentatus* JORDAN and EVERMANN, Bull. U. S. Fish Comm. 23 (1903) (1905) 393, fig. 171; poor figure.

*Acanthurus lineolatus* GÜNTHER, Cat. Fishes 3 (1861) 366; Fische der Südsee 1 (1875) 112, pl. 73, fig. A; excellent figure; STEINDACHNER, Denkschr. Ak. Wiss. Wien 70 (1900) 493.

Dorsal IX-24 or 25; anal III-23.

The depth is twice, the oblique head 3.45 to 3.7 times in length; body broadly ovoid, strongly compressed laterally, the greatest depth just before origin of ventrals, anterior profile convex from dorsal to below eyes, snout slightly concave; the small mouth low, with 6 teeth on each side of upper jaw; the elongate snout 1.4 to 1.5 times in head; eye 3.4 to 3.7 times in head, 2.5 to 2.6 times in snout; interorbital space rather broad, rounded, moderately low, 2.8 to 3.3 times in head; posterior margin of preopercle oblique, inclined about  $45^\circ$ , the angle beneath or in advance of anterior margin of eye, its depth 2 or 2.1 times in head; opercular margin steeply rounded, nowhere angulate; nostrils close together, the anterior one with a large membranous flap on its posterior margin, the posterior nostril with a more or less evident thin marginal membrane; first dorsal spine very low, concealed in thick skin, the last one longest, 1.7 times in head; anterior dorsal rays a trifle more or less in length than posterior dorsal spine; soft dorsal and anal similar in shape, the fins angulate posteriorly; third anal spine 1.9 to 2.25 times in head, anal rays a little lower than dorsal rays; pectoral a little longer than head; first ventral ray attenuate, equal to head; caudal lunate, upper lobe elongate, running to a sharp point, much longer than head, 2.5 to 2.75 times in length; caudal spine slender, very long pointed, 2.8 to 3.4 times in head.

Color in alcohol uniform brown, the sides dotted with paler, the dots forming irregular longitudinal lines which occur also

on the scaled part of vertical fins; dorsal and anal brown to dark brown, with a more or less evident blackish marginal line; pectoral pale brown; caudal paler posteriorly, with a white marginal line; a conspicuous black spot in axil of dorsal and anal. In life the pale dots and lines are blue.

Here described from a specimen, 117 millimeters long, from Sitankai, and two specimens, 104 and 107 millimeters in length, from Puerto Galera, Mindoro. The Bureau of Science collection contains a specimen, 98 millimeters long, collected by me at Sialat Point, Catanduanes. This species is common in the Hawaiian Islands, and ranges throughout the tropical Pacific from Marcus Island to the Samoan and Society Islands.

**ACANTHURUS BLEEKERI** Günther. Plate 14, fig. 2.

*Acanthurus bleekeri* GÜNTHER, Cat. Fishes 3 (1861) 335; BLEEKER, Ned. Tijds. Dierk. 1 (1863) 156; KLUNZINGER, Fische des Rothen Meeres (1884) 85; WEBER, Fische Siboga Exp. (1913) 318.

*Acanthurus mata* BLEEKER, Nat. Tijds. Ned. Ind. 7 (1854) 432; not of Cuvier and Valenciennes.

Dorsal IX, 24 or 25; anal III, 22 to 24.

The ovoid body strongly compressed laterally, broad anteriorly and tapering strongly toward caudal peduncle, its dorsal and ventral outlines alike, its depth 2.2 to 2.26 times, the short blunt head 3.8 times in length, its depth a fifth or a sixth more than its length; anterior dorsal profile high, strongly convex and very steep, forming a thin sharp ridge before dorsal fin; anterior ventral profile more gently and regularly curved; the large circular eye 3.8 to 4 times in head, twice or a little more than twice in snout, and 1.3 to 1.4 times in the broad, elevated interorbital; a smooth bony hump in front of upper part of eye; snout 1.8 to 1.84 times in head; posterior margin of preopercle inclined about 45°, its broadly rounded angle beneath anterior part of eye, its depth twice in head; the small terminal mouth has 9 small teeth on each side of upper jaw, their pointed tips lobate denticulate; teeth of lower jaw shorter, broader, with blunter lobate denticulate tips; dorsal and anal fins regularly rounded and convex, the dorsal spines of moderate size and strength, the first one partially concealed and very short, 7.83 times in head, second spine half again as long, the last one 1.5 times in head; the dorsal rays equal the longest spine, gradually decreasing in length posteriorly, the last three much shorter and the fin angulate posteriorly; third anal spine twice in head, the anal rays similar to the dorsal in height and shape; depth of caudal peduncle 4 times in head; caudal

lunate, with sharply pointed lobes, the upper the longer, its length usually 3 times (2.87 to 3) in length; pectoral a little longer than head, about 3.3 times in length; ventral pointed, about 1.25 times in head; the sharp-pointed caudal spine has a short posteriorly projecting point, its length three-fourths an eye diameter.

Color in alcohol uniform reddish brown, with traces of longitudinal lines on sides; 7 longitudinal blue lines on side of head, the upper one running along lower margin of eye, the three upper ones running across snout and uniting with those on the other side; a similar blue band across interorbital, from eye to eye; dorsal and anal darker brown than body, with vestiges of a black spot in posterior axil of each; the other fins same color as body. When fresh the axillary spots were distinct.

According to Bleeker the body color is brownish red with about 30 longitudinal blue lines; the violet-blue dorsal and anal each with 5 to 7 longitudinal yellow bands on the rays, the upper margin violet, each with a black spot posteriorly in the axil; the caudal blackish brown anteriorly, violet-brown posteriorly. These marks have all disappeared in my specimens.

The above description is based upon one specimen, 184 millimeters long, collected by Alvin Seale at Zamboanga, Mindanao, and 6 specimens, 163 to 185 millimeters long, obtained by the Bureau of Science collector G. A. Lopez, at Mariveles, Luzon.

The color of 6 fresh specimens, 150 to 188 millimeters in length, from Agutaya, one of the Cuyo Islands, was chocolate brown, with numerous longitudinal, more or less wavy blue lines on the sides, most distinct and broadest on the ventral half, those on the breast very broad; 7 longitudinal blue lines on side of head, the three upper ones uniting with those of the other side; a wider blue band from eye to eye, across interorbital; the region in front of, below, and behind eye more or less yellow; dorsal with a deep black longitudinal band below its base and a blue stripe above the black one; dorsal and anal chocolate brown, anal with a blue stripe along its base and two longitudinal blue stripes along its middle; the caudal and ventrals were brown like the body, the pectoral blackish basally, the posterior margin clear.

A large specimen, 270 millimeters long, also from Agutaya, has about 33 wavy blue longitudinal lines on body, counting across the body behind the pectoral. We also have two specimens, 190 and 158 millimeters long, from Subic Bay, and three specimens of medium size from the coast of Antique Province,

Panay. At the latter place it is very abundant, the Japanese fishermen bringing large quantities from there to Manila.

This distinct species was obtained by Bleeker at Batavia, Java, and Halmahera, and by Weber at Macassar, Celebes. It was also recorded from the Red Sea by Klunzinger. According to Weber it reaches a length of 300 millimeters.

*ACANTHURUS DUSSUMIERI* Cuvier and Valenciennes. Plate 14, fig. 3.

*Acanthurus dussumieri* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 147; GÜNTHER, Cat. Fishes 3 (1861) 335; Fische der Südsee 1 (1875) 112, pl. 72.

*Hepatus dussumieri* JORDAN and EVERMANN, Bull. U. S. Fish Comm. 23<sup>1</sup> (1903) (1905) 390, fig. 169; SEALE and BEAN, Proc. U. S. Nat. Mus. 33 (1907) 247.

*Teuthis argenteus* JORDAN and FOWLER, Proc. U. S. Nat. Mus. 25 (1903) 553.

*Teuthis dussumieri* JENKINS, Bull. U. S. Fish Comm. 22 (1902) (1903) 477.

Tagalog names, *indongan* and *samara*.

Dorsal IX-24 or 25; anal III-24.

Body deep, ovate, upper and lower profiles nearly evenly convex, or in very large specimens upper profile much more convex or even almost protuberant, depth 1.93 to 2.4 times, head 3.75 to 4 times in length; head deeper than long, nape boldly arched, snout steep or sometimes bulging forward, about 1.85 times in head; eye 4.4 to 4.6 times in head and 2.4 to 3.1 times in snout; interorbital very high, convex, its height 1.2 to 1.25 times eye, its breadth 2.85 times in head; mouth small, low, terminal, with 12 teeth on each side in upper jaw; rear margin of preopercle very oblique, its lower posterior angle beneath anterior portion of eye or even in front of a perpendicular from forward margin of eye; the circular anterior nostril has a thin membranous margin becoming a flap posteriorly; posterior nostril directly behind and much smaller; first dorsal spine very short and concealed in thick skin, the others increasing in length to the last, which is 1.77 to 1.9 times in head; soft dorsal of nearly uniform height, the longest rays 1.5 to 1.6 times in head, the last rays shortened and the fin angulate posteriorly; third anal spine 2.28 to 2.5 times in head, the soft anal like dorsal in shape, the longest ray about 1.75 times in head; the angulate pectoral equals or is a little longer than head; caudal peduncle thick, somewhat compressed dorsally, its depth 3 or a little less than 3 times in head; the large broad caudal lunate, with acute tips, 2.95 to 3.1 times in length; the pointed ventrals extend upon anal, about 1.4 times in head; the large caudal spine varies much in length and

thickness, 3 to 7.25 times in head; lateral line concurrent with dorsal profile, descending opposite to or before posterior end of dorsal to caudal spine.

Color in alcohol uniform brown, with a broad pale interocular band beginning behind each eye, and numerous dark brown longitudinal lines on nape, snout, sides of head, and breast; often these lines disappear after a time; the dorsal and anal may each have 3 or 4 longitudinal blue stripes and a basal band of the same color; pectoral dark anteriorly, with a yellow or clear transverse bar on posterior margin.

Fresh specimens were brown, the breast blackish brown, with many longitudinal wavy blue lines on head and body, and a broad bright yellow or orange band from behind eye forward around forehead to behind the other eye; a yellow bar at base of pectoral; the central part of caudal dark dull blue with numerous darker or blackish spots, the upper and lower margins sometimes orange; dorsal orange or yellow, the last few rays dull violet or dusky, with a dull yellow basal band and a blue band above it, a marginal blue or black line, and 3 or 4 more or less well-defined blue longitudinal lines, most evident posteriorly; the yellow anal slaty or bluish dusky posteriorly, with a blue basal band, a blue marginal line, and 3 or 4 blue longitudinal lines; ventral pale yellow, the membrane bluish; caudal spine brown with a black sheath.

The above description is from a specimen, 325 millimeters long, from Olongapo; one, 280 millimeters long, from Linapacan Island, Palawan Province; and one, 330 millimeters long, from Agutaya Island.

A specimen, 310 millimeters long, with a depth of 160 millimeters, was caught by me at Sitankai with hook and line. In life the brown body was marked with blue longitudinal vermiculations, the head sprinkled with a few blue dots; from behind eye a broad lemon yellow band extended forward across eye nearly to middle of forehead, but did not quite meet its fellow; a broad band of yellow on upper lip; the dorsal and anal were each dark lemon yellow with a broad basal band and 4 horizontal parallel stripes of lavender-blue; the pectoral was dark yellow-brown anteriorly, becoming bright lemon yellow posteriorly, with a clear margin; the ventral rays were dark yellow. In alcohol the color markings all disappeared, leaving the fish uniformly dark brown, with but a trace of the ocular band, and some brown vermiculations on the breast.

A female, 320 millimeters long, caught at Agutaya, one of the Cuyo Islands, during the first week in February, 1927, was nearly ready to spawn.

This species is abundant around rocky reefs and is brought to the Manila and Iloilo markets in considerable quantities by Japanese fishermen who catch it by the muro ami net method in the Visayas, especially about Sibuyan, Masbate, Tablas, and Bantayan.

I have examined numerous specimens and find them subject to very considerable variation in shape and color. The yellow interocular band is always present, though sometimes not entire across the frontal region, and separates this species at once from all related species. It is usually crossed by a longitudinal blue bar on its lower part, with another blue bar below it; the blue lines on the snout are wider than those on the body. This fish travels in schools of a dozen or so up to those containing several hundred. It takes the hook freely but is difficult to catch because its mouth is proportionately very small.

Seale and Bean had a specimen from Zamboanga.

Dussumier's surgeon fish is very common in the Hawaiian Islands and undoubtedly is equally abundant in all the intervening island groups between Honolulu and Palawan. The type specimen described by Valenciennes came from Mauritius.

**ACANTHURUS MARGINATUS** Cuvier and Valenciennes. Plate 3, fig. 2.

*Acanthurus guttatus* KITTLITZ, Mus. Senckenb. 1 (1834) 195; not of Bloch and Schneider.

*Acanthurus marginatus* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 162; GÜNTHER, Cat. Fishes 3 (1861) 333.

Dorsal IX-24; anal III-22.

Body ovoid, its greatest depth behind ventral fins, 1.91 to 1.93 times in length; anterior profile declivitous, boldly convex from dorsal to level of lower orbital margin, then more or less concave to tip of snout; head 3.33 to 3.57 times in length, placed obliquely, its depth equal to its length; ventral profile uniformly and moderately convex from lower lip to caudal peduncle; the concave snout 1.35 to 1.5 times in head; eye rather high up and anteriorly, 3.25 to 3.375 times in head and 2.25 to 2.5 times in snout, its anterior margin half or three-fourths its own diameter from anterior interorbital profile; interorbital broadly rounded, 3 times in head, twice or a little more than twice in snout; posterior margin of preopercle steeply inclined, forming

an angle of about  $45^{\circ}$ ; its lower posterior angle obtusely angled, beneath anterior margin or anterior third of eye, its depth 2 to 2.25 times in head and about 1.5 times in snout; the opercular margin forms a broad bold curve; mouth low, small, with 11 or 12 teeth in upper jaw, their round pointed tips crenulate laterally as well as terminally; dorsal spines of moderate strength, the first one very short but scarcely concealed, its tip more or less evident, the last spine 1.6 to 1.8 times in head; soft dorsal a little higher than last dorsal spine, with an acutely pointed posterior angle; third anal spine 2 to 2.25 times in head; the soft anal equals or nearly equals soft dorsal in height and is of the same shape; depth of caudal peduncle 2.5 to 2.7 times in head; caudal deeply lunate, with elongate pointed tips, the upper the longer, a third or more longer than head, 2.3 to 2.5 times in length; caudal spine slender, with an elongate point and a short posterior point, 2.7 to 2.8 times in head; pectoral a little longer than head; first ventral ray elongate, with filiform tip, its length a trifle more or less than head.

Color in alcohol uniform brown or chocolate brown, the vertical fins with a blackish brown linear margin; pectorals paler than body, the other fins concolorous or darker; the sides of head below level of eye and the body above pectoral base sprinkled with small circular whitish spots; a very deep chocolate brown spot in axil of dorsal and anal; a fine whitish line forms the posterior margin of caudal; two specimens have some curved, nearly vertical pale lines on sides of snout.

Here described from 4 specimens, 77 to 93 millimeters in length, obtained in the China Sea just outside Manila Bay, near Mariveles Point. This species was collected by Kittlitz at Laganor, one of the Caroline Islands, and has not been obtained since. The spots on the head were evidently blue in life, just as described by Kittlitz. My determination cannot be absolute, as I have seen neither authentic specimens nor the original description, but I have little doubt of its correctness. I prefer this disposition to calling it new.

*ACANTHURUS NIGRORIS* Cuvier and Valenciennes. Plate 4. fig. 1.

*Acanthurus nigroris* CUVIER and VALENCIENNES, Hist. Nat. Poiss. 10 (1835) 152; WEBER, Fische Siboga Exp. (1913) 317.

*Acanthurus nigros* GÜNTHER, Cat. Fishes 3 (1861) 332; Fische der Südsee 1 (1875) 110.

? *Acanthurus bipunctatus* GÜNTHER, Cat. Fishes 3 (1861) 331.

*Hepatus elongatus* JORDAN and EVERMANN, Bull. U. S. Fish Comm. 23<sup>1</sup> (1903) (1905) 389, pro parte; ? JORDAN and RICHARDSON, Bull. Bur. Fisheries 27 (1907) (1908) 270.

Dorsal IX-24 or 25; anal III-23 or 24.

Depth twice, head 3.5 to 3.66 times in length; body ovate, much flattened laterally, anterior dorsal profile convex, declivitous, nearly straight from interorbital space to tip of snout, head small, with elongate snout, 1.4 times in head; eye small, 3.9 to 4.5 times in head and 2.8 to 3.2 times in snout; preopercle broad, deep, with very oblique rear margin, its lower angle rounded, beneath anterior margin of eye or before a perpendicular from eye, its depth about 1.85 times in head; mouth low down, inferior, with 6 broad teeth on each side of upper jaw; interorbital broad, high, convex, 3 times in head; depth of caudal peduncle 2.3 to 2.4 times in head; nostrils close together, anterior one with a thin membranous flap anteriorly and posteriorly, rear nostril elongate with a low membrane anteriorly; first dorsal spine low but not concealed, last one longest, 1.7 times in head; dorsal and anal similar in shape, acutely angulate posteriorly, the longest dorsal rays a little longer than the longest spine, about 1.5 times in head; third anal spine 2.1 or 2.2 times in head, the longest anal ray about 1.85 times in head; pectoral a trifle longer than head; the ventrals extend about to base of second anal ray, a little more or less than head in length; the deeply lunate caudal more than a fourth longer than head, about 2.7 times in length, tips attenuate, upper lobe longer; the caudal spine has a very long point, 2.7 to 2.8 times in head.

Color in alcohol uniformly brown or blackish brown, the lips and the dorsal and anal fins darker than body, with a black spot in the axils of the two fins; the caudal has a whitish line at its posterior margin; pectorals yellowish to brown; ventrals blackish; the margin of the groove in which the caudal spine lies black.

Here described from 3 specimens from Hamilo, Batangas Province, varying in length from 120 to 145 millimeters.

Jordan and Richardson recorded what is probably this species from Cagayancillo. I have two specimens from Guam, 45 and 50 millimeters long, which seem to belong to this species. They have but 5 teeth on each side in the upper jaw.

Elsewhere this species is known from the Pelew and Hawaiian Islands, the New Hebrides, and Samoa, and in the East Indies

from Rotti northward to the Karkaralong Islands a little south of Mindanao.

*Hepatus guntheri* JORDAN and EVERMANN, Bull. U. S. Fish Comm. 23<sup>1</sup> (1903) (1905) 388, fig. 168.

Dorsal IX-25 or 26; anal III-24 or 25.

The deep ovoid body strongly compressed laterally, the greatest depth just before anal fin, 1.7 to 1.87 times in length; anterior profile boldly convex from spinous dorsal to tip of snout, head 3.45 to 3.66 times in length, or the head proportionately larger in young specimens; snout long, about 1.25 in head, or 1.5 in young specimens; eye rather large, prominent, 3.5 to 3.8 times in head, 2 to 3 times in snout; in large old specimens it is proportionately much smaller, interorbital rather broadly rounded, not very high, 2.7 to 3 times in head; posterior margin of preopercle steeply inclined; the angle broadly rounded and beneath anterior nostril in well-grown specimens, its depth 1.6 times in head, 1.9 to 2 times in the young; the opercular margin gently and broadly curved; mouth small, low, inferior; nine teeth on each side in upper jaw, their tips long, pointed, crenulate or denticulate back on sides some distance; in young specimens often only 8 teeth are present; dorsal spines slender, the first one very short and concealed in the thick skin, the last one 1.4 to 1.56 times in head; the dorsal rays equal or a little higher anteriorly than the longest dorsal spine, 1.4 to 1.5 times in head, rounded posteriorly; third anal spine 1.92 to 2 times in head; the anal rays a little lower than the dorsal; slightly angulate posteriorly, 1.56 to 1.84 times in head; pectoral a little

less than head, its upper rays elongate; the pointed first ventral ray reaches beyond base of third anal spine, 1.2 to 1.25 times in head; caudal more or less lunate, upper lobe elongate and pointed, 2.7 to 2.9 times in length; the depth of the flattened caudal peduncle 2.4 to 2.6 times in head; the short, broad caudal spine has a short posterior projection, its length 3.33 to 3.8 times in head, equal to eye, or twice in eye in young specimens.

In life the color is uniformly brown, with a narrow longitudinal black band on the scaly base of dorsal and anal fins, and a blue band above it; the dorsal has 4 or 5 longitudinal orange bands alternating with blue or lavender bands, the margin with a black line; anal like dorsal; caudal membranes blue, with a blue crossband on posterior margin; pectoral blackish brown, with a broad yellow posterior margin, or may be nearly all yellow; caudal spine pale or whitish, in a black area; a yellowish area about eye.

In alcohol the color is brown to blackish brown, with a more or less distinct wide pale or whitish band on base of caudal; the bands on dorsal and anal disappear entirely; ventrals blackish.

Here described from a specimen, 169 millimeters long, from Honolulu, Hawaii, one from Jolo with a length of 135 millimeters, and two specimens, 79 and 81 millimeters long, from Zamboanga, Mindanao.

A fresh specimen, 185 millimeters long, from Manila Bay, was brownish black, becoming bluish black below; the dorsal with 5 longitudinal pale dull yellow and 4 blue bands; a deep blue band on its base, with a narrow yellow band below it; a black line along margin; the anal had 4 yellow and 4 blue bands; the pectoral was blackish above, the outer third lemon yellow, its inner surface dusky greenish yellow merging into lemon yellow marginally; the iris was pale golden; starting behind eye was a lemon yellow bar which extended forward of eye upon snout, its lower margin a broad dark blue line; the lips were dark blue, with a lemon yellow spot behind their posterior angle; the caudal had an obscure pale basal crossband, the fin deep black posteriorly; the caudal spine and sheath were black.

A specimen, 340 millimeters long, collected in the lagoon at Pearl Bank, has the depth 2 times, the head 3.77 times in the length; snout 1.38 times, eye 5.6 times in head and 4 times in the long, boldly convex snout; nape laterally compressed, ridge-like; the longest dorsal spine twice, the longest rays 1.6 times in head; anal a little lower than dorsal, both fins angulate pos-

teriorly; caudal spine 4.7 times in head, and nearly a fourth longer than eye.

Small specimens have the head differently shaped, sometimes the profile from dorsal to tip of snout forming a steep, almost straight line; a conspicuous whitish or pale band is often present on the basal portion of caudal, its anterior margin sharply defined but merging gradually into brown posteriorly.

In addition to the above, I have examined many living and fresh specimens in various parts of the Islands, and have studied alcoholic specimens ranging in length down to 29 millimeters, as follows:

Mission, Cagayan Province, 1.  
 Paraair, La Union Province, 1.  
 Hundred Islands, Pangasinan  
 Province, 1.  
 Subic Bay, 1.  
 Manila, 1.  
 San Miguel Bay, Camarines  
 Sur Province, 1.  
 Calapan, Mindoro, 6.

Bantayan Island, 1.  
 Guimaras Island, 1.  
 Zamboanga, Mindanao, 1.  
 Tubigan Island, Sulu Province,  
 5.  
 Pearl Bank, Sulu Province, 2.  
 Sibutu, Sulu Province, 2.  
 Sitankai, Sulu Province, 1.  
 Sandakan, Borneo, 1.

This handsome species attains a length of 450 millimeters, and is common about submerged rocky reefs, traveling in small schools like flocks of sheep. Many living specimens from Puerto Galera and Calapan, Mindoro, have been kept under observation in the Bureau of Science aquarium. This species is subject to very considerable variation in shape, the proportions of the eye, and color markings; the caudal spine also varies a good deal in length, but is always relatively stout and short. In alcohol the color markings, including the bands on the fins, disappear entirely as a rule.

The synonymy of this species is in a deplorably confused condition and I make no claim to having clarified the situation. However, my extensive observations have convinced me that the separation of *Acanthurus blochi* or *A. guntheri* from *A. matoides* as distinct species is not justified, and that there is no definite boundary line between those with a large and those with a small eye, those with banded and those with plain vertical fins, and those with convex and those with nearly straight anterior dorsal profile.

This species has been recorded from Zamboanga and Jolo by Evermann and Seale; from Calayan, one of the Babuyan Islands, and Aparri, by Jordan and Richardson; and from Cebu by Fowler and Bean.

*Acanthurus matoides* was originally described from Oualan, one of the Caroline Islands. It is known from the east coast of Africa, the Red Sea, and Ile de France to the north coast of Australia, and the Hawaiian and Society Islands in the South Pacific Ocean.

*ACANTHURUS MINDORENSIS* Herre, sp. nov. Plate 4, fig. 2.

Dorsal IX-26; anal III-23.

The oblong ellipsoid body very much compressed laterally, depth at origin of ventrals 2.3 times in length; head strongly oblique, its length 3.4 times in total length; anterior dorsal profile convex from origin of dorsal to level of lower margin of eye, the rest concave; the thin concave snout long, 1.38 times in head; eye 4.16 times in head, high up, 3 times in snout; the broad, low, gently rounded interorbital 2.94 times in head and nearly thrice eye; posterior margin of preopercle very steep, the angle very obtuse, rounded, its depth 1.85 times in head, and three-fourths the length of snout; mouth very low down, with protuberant jaws, inclined diagonally downward and forward, with 8 broad teeth on each side in upper jaw, their tips rounded, denticulate laterally for most of their length; teeth in lower jaw broader, not denticulate so far back, 8 or 9 on each side; dorsal spines rather stout, the first one longer than in most species and not concealed, the last one  $\frac{1}{2}$  as long as snout and 1.78 times in head; dorsal rays equal last dorsal spine in height, the posterior rays broadly rounded, not elongate; third anal spine much lower, 2.62 times in head; the anal resembles dorsal but is lower, the posterior rays longest, a little more than twice in head; the broad caudal lunate, the lobes not produced, a fifth longer than head, 2.83 times in length; depth of caudal peduncle 2.77 times in head; caudal spine narrow, with a long slender point, equal to eye in length; pectoral shorter than head, 1.16 times in head; ventral pointed, tips not elongate, 0.7 as long as head.

Color in alcohol black, sides of head and breast blackish brown; at base of caudal fin a deep brown ring; all the fins black.

Here described from the type specimen, 170 millimeters long, from Calapan, Mindoro, which has been kept alive a long time in the Bureau of Science aquarium.

I place here a specimen, 184 millimeters long, recently collected at Bantayan Island; dorsal IX-25; anal III-23; teeth above 9, below 10; it is much deeper proportionately, depth

1.88 times in the length, but does not differ materially in other proportions. The color in alcohol is blackish brown, the vertical fins, posterior part of pectoral, and the ventrals black; the caudal is lunate, its central portion black to the posterior margin.

*ACANTHURUS PHILIPPINUS* Herre, sp. nov. Plate 5, fig. 1.

Dorsal IX-24, sometimes 23; anal III-23 or 24.

Body elongate, ellipsoid-ovoid, greatest depth between ventral and anal fins and 2.16 to 2.2 times in length, head 3.5 to 3.85 times in length; anterior dorsal profile boldly convex, forming a smooth curve from dorsal to mouth, or the region above eyes nearly straight and a bulge before eyes; ventral profile uniformly and strongly curved from mouth to caudal peduncle; snout twice to 2.19 times in head, the circular eye of moderate size, 3.5 to 3.7 times in head and 1.6 to 1.8 times in snout; interorbital rather low, 2.85 to 3 times in head; posterior margin of preopercle steeply inclined, often more or less bowed, the angle obtuse, the depth 2.3 to 2.4 times in head; mouth very small, terminal, a little below median line, lips thin and not prominent; the slender teeth much smaller than in any other Philippine species, with narrow, pointed, finely serrate tips, 10 on each side in upper jaw and 12 to 14 on each side in lower jaw; nostrils small, inconspicuous, the anterior one with a small posterior flap of skin, the posterior one partly concealed by skin; first dorsal spine very low, embedded in thick skin, the last spine twice, down to 1.8 times in head; dorsal rays equal to or usually a little higher than last spine, the posterior rays round pointed; third anal spine 2.2 to 2.6 times in head; anal rays equal to dorsal, posterior rays a little higher, forming an elongate, acutely pointed angle; caudal peduncle thick, somewhat flattened above and below, its depth 2.6 to 2.9 times in head; caudal deeply lunate, tips elongate, the upper one narrow, pointed, and much the longer, 2.4 to 2.75 times in length; pectoral longer than head, 3.15 to 3.4 times in length; ventrals short, broad, 5 to 5.2 times in length; caudal spine about 3 times in head, slender, with an elongate sharp point and a short sharp backward projection.

Color in alcohol dark purplish brown, the vertical fins blackish or deep chocolate; caudal pale brownish yellow; pectoral and ventrals black or deep brown. The caudal was evidently yellow in life, the base more or less dusky.

Here described from 9 specimens, 109 to 143 millimeters in length, from Calapan, Mindoro. The pale caudal and the

meters long has no horns, while other specimens two-thirds as large have large horns. The presence or absence of horns above the eyes is therefore not a specific character.

Even the smallest specimens are entirely distinct from *Z. canescens*, which cannot be considered as the young of *Z. cornutus*.

This species has an enormous range, occurring from Zanzibar and the east coast of Africa to the Hawaiian, Samoan, and Tonga Islands, and on eastward to the Revillagigedo Islands off the coast of Mexico. Cuvier and Valenciennes had specimens, 250 millimeters in length, but state that it becomes larger.

## ERRATA

### VOLUME 33

*Note.*—Dans la description du *Ceratosolen imbecillus* sp. nov., p. 315, j'ai donné erronément l'antenne de la femelle composée de 10 articles, au lieu de 11, et j'ai décrit pour 4<sup>me</sup> article le 5<sup>me</sup>. Le 4<sup>me</sup> article, au contraire, est très petit mais distinct.

Ceci posé, *C. imbecillus* est presque certainement synonyme de *C. hewitti* Waterst. de l'Île de Borneo.

# *Polypodium*—Continued.

*(Phymatodes) albido-squamatum*, 244.  
*(Phymatodes) glauco-pruinatum*, 244.  
*Pomacentrus lunula* Lacép., 52.  
*tripunctatus* Cuv. & Val., 297.  
*Priodon annularis* Cuv. & Val., 452.  
*annulatus* Quoy & Gaimard, 454.  
*hezacanthus* Bleeker, 463, 464.  
*Prioniturus cyaneiceps* Sharpe, 228.  
*Prionurus caume* Lesson, 464.  
*Priopsis buruensis* (Bleeker), 296.  
*gymnocephalus* (Lacép.), 296.  
*Pristis microdon* Latham, 303.  
*Prognathodus longirostris* Bleeker, 16.  
*Proparathelaira* T. T., 378.  
*plumosa* T. T., 378.  
*Propharichaeta* T. T., 390.  
*philippina* T. T., 390.  
*Prosaptia*, 239, 254.  
*Pseudocryptera*, 369.  
*Pseudodexia*, 366.  
*Pseudokea* T. T., 393.  
*neowinthemioides* T. T., 393, 394.  
*Pseudofersia*, 220, 223.  
*spintifera* (Leach), 220.  
*Pseudolynchia* Bequaert, 219.  
*maura* (Bigot), 219.  
*Pseudorectocera* T. T., 385.  
*albifacies* T. T., 385.

## R

*Rabdophorus* Swainson, 20.  
*Ray tapis*, 407.  
*Rhinogobius flavoventris* Herre, 276, 207.  
*Rhodogyne philippensis* T. T., 388.  
*Rhytidoceros plicatus* Forst., 232.  
*Riring*, 3.

## S

*Saccoloma*, 239.  
*Salias*, 405.  
*Samara*, 425.  
*Samaral*, 405.  
*Sameodes alexalis* Schaus, 325.  
*ennoduisalis* Schaus, 326.  
*finbaralis* Schaus, 325.  
*oduphalis* Schaus, 326.  
*ulricalis* Schaus, 325.  
**SANTOS, IRENE, and AUGUSTUS P. WEST.** Esters of alpha linolic acid tetrabromide (methyl, ethyl, propyl, isopropyl, and allyl) from lumbang oil, 199.  
*Surathrodus* Gill, 20.  
*Scatophagidae*, 2, 7, 109.  
*Scatophagus* Cuv. & Val., 2, 7, 109.  
*argus* (Bodd.), 8, 109.  
*argus* Cuv. & Val., 8.  
*argus* (Gmel.), 294, 297, 303.  
*ornatus* Cuv. & Val., 8.  
**SCHAUS, W.** New species of } *Pyraustinae*  
 from the Philippine Islands, 313.  
*Schizoloma*, 240.

- Scyphularia* Fée, 240, 242, 245, 254.  
 pentaphylla, 254-256.  
*pyncocarpa* (Brack.) Copel., 254, 255.  
*simplicifolia* Copel., 254, 256.  
*sinusora* Copel., 254, 255.  
*triphylla* (Hook.) Fée, 254, 256.  
*Serenthia formosana* Mats., 312.  
*sedalis* Drake, 312.  
*vicinalis* Drake, 311.  
*Sicus* Scop., 331, 332.  
 ferrugineus L., 335.  
 vaginatus Kröb., 335.  
*Sillago sibama* (Forsk.), 297, 308.  
 Simbad, 301.  
*Sisyropododexia* T. T., 367.  
 luteicornis T. T., 367, 368.  
*Spalthidexia*, 367.  
*Spilopelia tigrina* (Temm. & Knip.), 217, 219.  
 sp., 205.  
*Spylosia*, 388.  
 Staphyliniden der Philippinen, 399.  
*Stomoxys*, 117, 119.  
 calcitrans, 116, 118, 119, 121-126, 138.  
 gemiculatus, 116.  
*Strongyloneura nepalana* T. T., 376.  
*Strongyloneuropsis* T. T., 376.  
 malayensis T. T., 376.  
*Sturmiodoria* T. T., 391.  
 facialis T. T., 391, 392.  
*Stylomaster*, 331.  
 bakeri Bezzi, 331, 335.  
 orientalis Brun., 331, 335.  
*Stylomasterinae*, 331.  
*Sumatrodexia*, 378.  
 Surgeon fishes, 403.  
*Sylepta azadesalis* Schaus, 320.  
 banosalis Schaus, 318.  
 berambalis Schaus, 318.  
 cathanalis Schaus, 318.  
 chalybifascia Hampson, 322.  
 dottoalis Schaus, 321.  
 elphegalis Schaus, 320.  
 marcareaalis Schaus, 321.  
 mildredalis Schaus, 321.  
 petronalis Schaus, 319.  
 simcalis Schaus, 319.  
*Symgramma*, 240.  
*Synnum* sp., 268.

## T

- Tabanidae*, 119.  
*Tabanus*, 116, 117.  
 albimedium, 119.  
 evansi, 118.  
 striatus, 118, 119, 124-131, 137.  
*Taenioides caeculus* (Bl. & Schn.), 297.  
 cirratus (Blyth), 303.  
*Taenitis*, 240.  
 Taxan, 298.  
 Talahib, 296.  
 Talocogan, 105.  
 Tapay tapay, 20, 81.  
*Tapinidium*, 240, 254.

- Taurichthys varius* Cuv. & Val., 79.  
*chrysostramus* Bleeker, 80.  
*macrolepidatus* Bleeker, 76.  
 Tawilis, 274, 295.  
 Teiro, 81.  
*Tetragonopterus* Bleeker, 20.  
 Klein, 19.  
 auriga Bleeker, 30.  
 bennettii Bleeker, 65.  
 collaris Bleeker, 41.  
 ephippium Bleeker, 56.  
 fasciatus Bleeker, 62.  
 kleini Bleeker, 58.  
 lincolatus Bleeker, 47.  
 melanotus Bleeker, 44.  
 mertensi Bleeker, 35.  
 miliaris Bleeker, 68.  
 octofasciatus Bleeker, 40.  
 ornatus Bleeker, 42.  
 polyepis Bleeker, 74.  
 punctato-fasciatus Bleeker, 60.  
 rafflesi Bleeker, 38.  
 selene Bleeker, 54.  
 speculum Bleeker, 66.  
 triangulum Bleeker, 26.  
 trifasciatus Bleeker, 63.  
 ulienensis Bleeker, 46.  
 unimaculatus Bleeker, 61.  
 vagabundus Bleeker, 32.  
 zanthurus Bleeker, 35.  
*Tenthis achilles* Fowler, 415.  
 alba Jordan & Evermann, 416.  
 annularis Fowler, 430.  
 argentea Jordan & Fowler, 425.  
 atramentatus Jordan & Evermann, 422.  
 australis Gray, 407.  
 dussumieri Jenkins, 425.  
 guntheri Jenkins, 430.  
 hepatus L., 435.  
 lineatus Seale, 420.  
 matoides Jenkins, 430.  
 olivaceus Jordan & Evermann, 413.  
*Therapon cancellatus* Cuv. & Val., 303.  
 jarbua (Forsk.), 297, 303.  
*Theraponidae* sp., 297.  
 Thermal and photochemical decomposition of  
 caryophyllene nitrosite, 187.  
*Tholichthys* Gthr., 1, 10, 20.  
*Thripinax hargilli* Sharpe, 217.  
*Tingitidae* from the Far East and Madagascar  
 (Hemiptera), 307.  
*Toxotes jaculatrix* (Pallas), 297, 303.  
*Trachypeplus bakeri* Drake, 308.  
 jacobsoni Horvath, 309.  
 Transmission of surra among animals of the  
 equine species, 115.  
*Trichomanes canariense* L., 253.  
*Trichostylum fasciatum* T. T., 380.  
*Trogostelen* Copel., 240, 242, 251.  
 falcinellus (Presl) Copel., 251.  
*Trypanosoma brucei*, 116.  
 evansi, 117, 119, 120, 122-124, 129, 130,  
 133, 134, 136-138.  
 gambiense, 17.

## Trypanosoma brucei—Continued.

*lewisi*, 117.*theileri*, 136.

Tudlo-an, 448, 450, 455.

*Tutillodesia*, 368.TYLER-TOWNSEND, CHARLES H., New  
Muscoidea from the Philippines region,  
365.

## U

Umayi, 435.

*Urodexiomima* T. T., 366.*uramyoides* T. T., 366, 367.*Urocuantha* T. T., 365.*longipes* T. T., 365, 366.

## V

*Vaimosa macrognathus* Herre, 297, 303.*piapensis* Herre, 297.VALENZUELA, PATROCINIO, and FAR-  
RINGTON DANIELS, Thermal and  
photochemical decomposition of caryo-  
phyllene nitrosite, 187.VAN DRIEL, R. M., Note on frambesia in  
Sumatra, 205.
